Hydrologic Analysis

APPENDIX A

HYDROLOGIC ANALYSIS

Two different models were used to develop design flows for the primary and secondary systems. For each system analyzed, the hydrologic model(s) was selected based on the complexity of the stormwater conveyance system.

The US Army Corps of Engineers (USACE) HEC-HMS model was selected to model the primary systems defined as the main stems of Swift Creek, SCUT1, and Gum Swamp. HEC-HMS simulates the surface runoff response to precipitation for an interconnected system of surfaces, channels, and ponds. Input data for the HEC-HMS model was developed using topographic, land use, and soils maps in GIS to delineate and calculate the basin areas and SCS hydrologic parameters. The HEC-HMS model offers a variety of methods for simulating the rainfall-runoff response, hydrograph development, channel and pond routing. The selection of methods for the analyses is based on the study objectives, data availability, and watershed characteristics. The precipitation data for the 24-hour duration, NRCS Type III storm was used to represent the synthetic rainfall event. The NRCS curve number approach was selected to calculate runoff volumes from the precipitation data, and the sub-basin unit hydrographs for these flood volumes were developed using the NRCS lag times. Where appropriate, reservoir routing was selected to model attenuation behind culvert embankments.

For the secondary systems that may: (a) have significant backwater effects from rising water surface elevations within the Primary Systems, (b) have attenuation within drainage ditches or behind roadways, and (c) show a sensitivity to the timing response of runoff to rainfall, the Storm Water Management Model (SWMM) developed by the Environmental Protection Agency (EPA) was selected as the hydrologic and hydraulic model. The NRCS curve number approach was selected to calculate runoff volumes from the precipitation data, and the sub-basin unit hydrographs for these flood volumes were developed using the watershed width parameter. SWMM simulates the surface runoff response to precipitation for an interconnected system of surfaces, channels, and ponds. Input data for the SWMM model was developed using topographic data, land use data, and soils maps in GIS to delineate and calculate the basin areas and NRCS hydrologic parameters. The SWMM model offers a variety of methods for simulating the rainfall-runoff response, hydrograph development, and channel routing. One advantage to using SWMM to model both hydrology and hydraulics is that channel routing is modeled in the EXTRAN (hydraulics) block automatically based on the geometry and nature of the conveyance system. This eliminates the need to iterate between a hydrologic model and a hydraulic model to produce reasonable flows.

APPENDIX A

HYDROLOGIC ANALYSIS

Table A-1 lists the different systems and the modeling methodology applied to each system.

Table A-1: Project Area Model Selection

| Project Area | Model Selection |
|----------------------------|-----------------|
| Swift Creek Primary System | HEC-HMS |
| SCUT1 Primary System | HEC-HMS |
| Gum Swamp Primary System | HEC-HMS |
| Davenport Farm Road System | SWMM |

Watershed Delineation and Connectivity

Watersheds were delineated for the Primary Systems and the secondary system utilizing digital LiDAR data available from the State of North Carolina and the stormwater inventory. The preliminary watersheds were created using automated procedures in a GIS platform and then adjusted as necessary based on the conveyance system and known ridge lines. Each flood control project watershed for the Primary Systems was subdivided into sub-watersheds selected at hydrologically and hydraulically significant points, such as major roadway crossings, stream convergences, known problem areas, etc. Each sub-watershed for the secondary systems was selected as the area that drained to each inlet modeled on the secondary system. Forty-three (43) sub-watersheds were delineated for the Primary Systems ranging in size from 14 to 876 acres. Sub-watersheds were delineated as necessary for the secondary systems to accurately model the hydraulics of the system. The watershed maps included in Appendix C illustrate the sub-watershed and hydrologic connectivity for the primary system.

Soils

The NRCS curve number method uses basin characteristics, such as soil types and land use, to compute the runoff response. The infiltration rate of a soil influences the volume of surface runoff that results from given storm events. Soils with high infiltration rates produce lower runoff than soils with lower infiltration rates. The Soil Conservation Service has prepared soil maps for Pitt County that identify four primary soil groups. This data is available digitally and was obtained for the City of Greenville.

The groups (A, B, C, and D) correspond to decreasing rates of infiltration. A general description of the four soil groups taken from the USDA, SCS, NEH-4 (1972) is presented in Table A-2.

APPENDIX A

HYDROLOGIC ANALYSIS

Table A-2: Hydrologic Soils Groups

| Soil Group | Description |
|-------------------|--|
| A | Group A soils have high infiltration rates even when thoroughly wetted and consist chiefly of deep, well to excessively drained sand or gravels. These soils have a high rate of water transmission (greater than 0.3 inches per hour). |
| B | Group B soils have moderate infiltration rates even when thoroughly wetted and consist chiefly of moderately deep to deep, moderately well to well drained soils with moderately fine to moderately coarse texture. These soils have a moderate rate of water transmission (0.15 to 0.3 inches per hour). |
| C | Group C soils have slow infiltration rates when thoroughly wetted and consist chiefly of soils with a layer that impedes downward movement of water, or soils with moderately fine to fine texture. These soils have a slow rate of water transmission (0.5 to 0.15 inches per hour). |
| D | Group D soils have a very slow infiltration rate when thoroughly wetted and consist chiefly of clay soils with a high swelling potential, soils with a permanent high water table, soils with a clay pan or clay layer at or near the surface, and shallow soils over nearly impervious material. These soils have a very slow rate of water transmission (0 to 0.05 inches per hour). |
| A/D B/D | The first letter applies to the drained condition and the second to the undrained condition. For the purpose of hydrologic soil group, adequately drained means that the seasonal high water table is kept at least 60 centimeters (24 inches) below the surface. |

Soils within the watershed are predominantly NRCS hydrologic soil groups C soils, although seven (6) different hydrologic soil groups are represented in some quantity in the Swift Creek watershed (See Table A-3 and Appendix C).

Table A-3: Area Distribution of Hydrologic Soil Groups

| Soil Group | Total Area (acre) | Percent of Total Area |
|-------------------|--------------------------|------------------------------|
| A | 78 | 2% |
| B | 954 | 23% |
| C | 1,734 | 42% |
| D | 970 | 24% |
| A/D | 12 | < 1% |
| B/D | 345 | 8% |

Water cover makes up the remaining one (1) acre of the Swift Creek Watershed.

APPENDIX A

HYDROLOGIC ANALYSIS

Land Use

Land use is the watershed cover condition as it relates to the actual type of development and zoning within the watershed. Land use influences the runoff characteristics of a watershed, and combined with other basin characteristics, is used to determine the SCS curve number for the basin.

The existing zoned land uses for the Swift Creek Watershed were provided by the City of Greenville. These zoning maps were used to develop peak flows for the watershed. Twelve (12) land use categories were delineated within the Swift Creek Watershed based on the information provided and field observation of the current uses (See Appendix C).

In its entirety, the Swift Creek Watershed covers an area of approximately 4,100 acres (6.4 square miles). Land use in the watershed is about 55 percent built out as shown on the Existing Conditions Land Use Map included in Appendix C. Percentages of each existing and future land use groups and the correlating acreage are listed in Table A-4 below.

Table A-4: Swift Creek Watershed Land Use

| Land Use Category | Existing | | Future | |
|-----------------------------------|--------------|-----------------------|--------------|-----------------------|
| | Area (acres) | Percent of Basin Area | Area (acres) | Percent of Basin Area |
| Right-of-Way | 289 | 7% | 289 | 7% |
| Industrial | 4 | < 1% | 4 | < 1% |
| Commercial | 151 | 4% | 303 | 7% |
| Mixed Use/Office/Institutional | 425 | 10% | 411 | 10% |
| Office/Institutional/Medical | 22 | 1% | 20 | < 1% |
| Office/Institutional/Multi-Family | 100 | 2% | 100 | 2% |
| High Density Residential | 142 | 3% | 252 | 6% |
| Medium Density Residential | 374 | 9% | 488 | 12% |
| Low Density Residential | 553 | 14% | 482 | 12% |
| Very Low Density Residential | 243 | 6% | 1,521 | 37% |
| Conservation/Open Space | 584 | 14% | 224 | 5% |
| Agricultural/Cropland | 1,207 | 29% | - | - |

APPENDIX A

HYDROLOGIC ANALYSIS

NRCS Curve Numbers

The NRCS curve number approach was used in computing the runoff response. Runoff curve numbers (RCNs) were generated by using the NRCS document entitled Urban Hydrology for Small Watersheds, dated June 1986 and commonly referred to as TR-55. This method relates the drainage characteristics of the hydrologic soil group, land use category, and antecedent moisture conditions (AMC) to a runoff curve number. The runoff curve number and an estimate of the initial surface moisture storage capacity are used to calculate a total runoff depth for a storm in a basin.

The AMC refers to the total rainfall in a 5-day period preceding a storm and relates to the soil moisture condition at the beginning of the storm event. The AMC value can be used as a calibration tool in the hydrologic computations where AMC-1 represents "dry" conditions and AMC-3 represents "wet" conditions. The average antecedent moisture conditions (AMC-2) are generally considered most representative for the humid southeastern portion of the country and were used for the hydrologic calculations in this study.

Runoff curve numbers were determined for each sub-basin based on the soil group, land use, and average antecedent moisture condition for the area. The curve numbers calculated for this study are listed in Table A-5 below.

Table A-5: Curve Numbers Based on Land Use and Soil Groups

| Land Use Category | Soil Group | | | |
|---------------------------------------|------------|----|----|----|
| | A | B | C | D |
| Commercial | 89 | 92 | 94 | 95 |
| Conservation/Open Space/Agricultural* | 49 | 69 | 79 | 84 |
| Open Space, Good Condition | 39 | 61 | 74 | 80 |
| Very Low Residential | 49 | 69 | 79 | 84 |
| Low Density Residential | 51 | 68 | 79 | 84 |
| Medium Density Residential | 54 | 70 | 80 | 85 |
| High Density Residential | 61 | 75 | 83 | 87 |
| Office/Institutional/Multifamily | 77 | 85 | 90 | 92 |
| Right-of-Way | 83 | 89 | 92 | 93 |

*Assumed fair condition

For each sub-basin, the curve number was determined and weighted by area to calculate the composite curve number for each sub-basin. A summary of the hydrologic input data for the Primary Systems, including the runoff curve numbers, is shown in Table A-6. The detailed calculations are included in Appendix E (runoff curve numbers) and Appendix F (times of concentration).

APPENDIX A
HYDROLOGIC ANALYSIS

Table A-6: Summary of Hydrologic Input Data

| Drainage Basin ID | Drainage Area (acre) | Existing RCN | Future RCN | Lag Time* (minutes) |
|-------------------|----------------------|--------------|------------|---------------------|

APPENDIX A

HYDROLOGIC ANALYSIS

Rainfall

Rainfall distributions for Greenville are derived using the NRCS Type III standard distribution. Total rainfall volumes for the modeled frequency storms were based on data published on the NOAA website, http://hdsc.nws.noaa.gov/hdsc/pfds/orb/nc_pfds.html. Table A-7 shows the total rainfall volumes used for this study based on precipitation data collected in Greenville, North Carolina

Table A-7: Design Storm Rainfall Depths

| Design Storm | Rainfall Depth (in) |
|-------------------|---------------------|
| 2-year, 24-hour | 3.76 |
| 10-year, 24-hour | 5.81 |
| 25-year, 24-hour | 7.23 |
| 50-year, 24-hour | 8.47 |
| 100-year, 24-hour | 9.84 |

While the depth-duration-frequency curves are calculated based on real rainfall data, the rainfall data used for the SWMM and HEC-HMS models represent the Type III synthetic rainfall distribution. Actual runoff is based on several factors including rainfall intensity, duration and the antecedent moisture conditions of the watershed.

Hydrograph Translation

The lag time, as defined by the NRCS for use in the NRCS dimensionless unit hydrograph method, is the time, or lag, between the center of mass of rainfall excess and the peak of the unit hydrograph. The lag time is based on the sub-watershed time of concentration, or travel time, and is a function of the sub-watershed size, shape, slope, cover, and other basin characteristics. For the NRCS method, the sub-watershed lag time is calculated to be 0.6 times the time of concentration for each sub-watershed.

The times of concentration for the sub-watersheds were calculated from the methodology described in TR-55. A summary of the calculations is shown in Appendix F. The longest flow path is divided into three types of flow; overland flow, shallow concentrated flow, and channel flow. A spreadsheet was developed to tabulate the incremental travel times for each type of flow for each sub-basin. The incremental travel times were totaled and multiplied by 0.6 to compute the lag time for each sub-basin. The equation detailing the travel time for sheet flow is as follows:

$$T_t = \frac{.007 (nL)^{0.8}}{(P_2)^{0.5} s^{0.4}}$$

T_t = Travel Time in hours

n = Manning Roughness Coefficient (Paved=0.011, Unpaved=0.24)

APPENDIX A

HYDROLOGIC ANALYSIS

L = flow length in feet
P₂ = 2-year, 24 hour rainfall = 3.76 inches
S = slope of hydraulic grade line (land slope in ft/ft)

For shallow concentrated flow, the velocity (V) is calculated for either paved or unpaved sections by using the following equations:

$$\begin{aligned} \text{Unpaved } V &= 16.1345 (S)^{1/2} \\ \text{Paved } V &= 20.3282 (S)^{1/2} \end{aligned}$$

The travel time for shallow flow is then calculated by dividing the flow length (L in feet) by velocity as follows:

$$T_t = \text{Travel Time} = L / (3600 * V)$$

The open channel travel times are determined by a modified version of the Manning equation, which is as follows:

$$V = \frac{1.49 R^{2/3} S^{0.5}}{n}$$

V = Average full-flow velocity (ft/s)
R = Hydraulic radius (ft)
S = Slope of hydraulic grade line (ft/ft)
n = Manning roughness coefficient

Instead of a time of concentration parameter, the SWMM model uses a watershed width parameter to create the unit hydrograph used in the model that will translate the rainfall into runoff. The watershed width is a parameter unique to SWMM that typically represents the watershed area divided by the longest flow path. The width parameter is typically calibrated to flow gauge data, if available. The Swift Creek Watershed lacks flow gauge data, so the peak flows from SWMM were compared to flows developed using the Rational Method. Based on the flow comparison, the watershed widths for each basin were increased in some instances to produce reasonable flows. Increasing the watershed width parameters is not an uncommon practice for calibrating models for areas with gradual slopes and moderate conveyance systems.

APPENDIX A

HYDROLOGIC ANALYSIS

Channel Elements

Flood peaks attenuate, or reduce, as they travel downstream due to the storage characteristic of the stream reach. The Muskingum-Cunge routing method in HEC-HMS was selected to define the storage characteristic of selected stream reaches in the Swift Creek Watershed. It can be described as a hydrologic routing method based on physical parameters of the channel and floodplain. Input data for this method consists of representative channel/floodplain sections, reach length, Manning's roughness coefficient, and channel bed slope. This method provides advantages over other hydrologic techniques based on the relative size and slope of the channels and floodplains in the watershed.

Structure and Pond Routing

Reservoir storage routing was used for routing hydrographs through the storage areas upstream from undersized structures (culverts). HEC-HMS is able to model the effects of an undersized culvert through inputs defining the relationship between water volume or area and elevation and the relationship between outflow and water surface elevations. The relationship between outflow and water surface elevations is developed using an iterative process between HEC-HMS and HEC-RAS. A rating curve generated using HEC-RAS defines the outflow of the water leaving this system.

Structures having fill heights greater than or equal to 50% of the height of the structure were assumed to provide significant peak flow attenuation and, therefore, were routed in the HEC-HMS model. In addition, any structure which exhibited significant upstream floodplain storage or significant backwater from the HEC-RAS model output would be analyzed for providing peak flow attenuation.

For each structure, the cutoff point in the backwater pool was determined where the structure routing ends and upstream channel routing begins. This determination was necessary so that available storage areas calculated for channel and structure routing did not overlap. The following procedure was used for this determination:

- The approximate limit of the 100-year frequency flood backwater pool was delineated in the topographic map.
- The distance from the upstream face of the structure to the upstream limit of the pool was measured.
- From the upstream end of the backwater pool, a distance equal to 20% of the total pool length was measured in the downstream direction and the point marked on the topographic map.
- Through this point a line was drawn perpendicular to the contour lines.
- This line was then designated as the cutoff point to be used as the upstream limit of the channel routing.

APPENDIX A

HYDROLOGIC ANALYSIS

For each structure, the elevation-storage relation for the Modified Puls method was derived by calculating the surface area of the topographic contours from the upstream face of the structure to the routing cutoff point associated with the structure. A pair of "SA" (storage area) – "SE" (elevation) records, the elevation-storage relation for each structure was input from the delineated information. To avoid interpolating storage areas for each stage-discharge point, a separate stage-discharge relation was entered into the HEC-HMS model on a pair of "SQ" (discharge) – "SE" (elevation) records based on the HEC-RAS model output.

However, the method described in the previous paragraph does not account for the reduction in tailwater on the structure due to the attenuation effects of the upstream storage, which in turn can affect the stage-discharge relation of the structure. Therefore, an iterative process for storage structures was followed with an objective to obtain a set of peak discharge values, runoff volumes, and water surface elevations that are "balanced" between the two models. The process was initiated by inputting a set of discharges into the HEC-RAS model to develop a set of discharge-storage relations for each reach. This initial set of relations was input into the HEC-HMS model. These values were supplemented by the depth-storage relation for each structure.

The HEC-HMS model was run with these values to derive new discharges at downstream locations. These new values were input into the HEC-RAS model and it was recomputed. The new discharges and water surface elevations listed in the HEC-HMS summary output were compared with the discharges listed in the previous HEC-RAS run. When the values stabilized, the model was considered "balanced". If not then additional iterations were performed. Typically, three iterations are adequate to derive a balanced model.

Summary of Hydrologic Model Results

The HEC-HMS model was used to compute peak runoff for the 2-, 10-, 25-, 50- and 100- year design storms for the existing conditions.

The results of the hydrologic model are summarized in Table A-8. The HEC-HMS input and output are included in Appendix H. Additionally, a CD is included in Appendix J and contains the digital files for the HEC-HMS model.

APPENDIX A

HYDROLOGIC ANALYSIS

Comparison of Peak Flows

For comparison purposes, flood peaks were estimated using the U.S. Geological Survey (USGS) publication entitled "The National Flood-Frequency Program – Methods for Estimating Flood Magnitude and Frequency in Rural and Urban Areas in North Carolina – USGS Fact Sheet 007-00" (2001) at key locations within the watershed. Table A-9 compares the peak flows determined from the USGS regional regression equations the Coastal-Plain region versus the peak flows from HEC-HMS. Additional, the peak flows from HEC-HMS were also compared to available FEMA flows.

Appendix B:

Hydraulic Analysis

APPENDIX B

HYDRAULIC ANALYSIS

The purpose of the hydraulic modeling analysis is to determine an existing level of flooding for the stormwater drainage network and to develop proposed solutions to mitigate flooding, on both the primary systems and the secondary systems. Three different modeling methodologies were used depending on the complexity and location of the conveyance system. For the primary systems comprised of Swift Creek, SCUT1, and Gum Swamp, the Hydrologic Engineering Center River Analysis System (HEC-RAS) was used for hydraulic modeling. For the secondary system, SWMM was the selected model due to the complex nature of the system. Table B-1 lists the project areas that were modeled using each approach.

Table B-1: Project Area Model Selection

| Project Area | Model Selection |
|----------------------------|-----------------|
| Swift Creek Primary System | HEC-RAS |
| SCUT1 Primary System | HEC-RAS |
| Gum Swamp Primary System | HEC-RAS |
| Davenport Farm Road System | SWMM |

HEC-RAS Model

The HEC-RAS model calculates water surface profiles for steady, gradually varied flow, both sub-critical and supercritical, for user-specified discharges. The standard step backwater analysis for sub-critical flow was modeled for the Swift Creek, SCUT1, and Gum Swamp Primary System. The model calculates the effect of obstructions, such as culverts, and building structures in the channel and floodplain on the water surface profile. The hydraulic computations are based on the solution of a one-dimensional energy equation with energy loss due to friction evaluated by Manning's equation.

Input data for the HEC-RAS computer model includes the following:

- Cross-section geometry of the channel and floodplain.
- Roughness coefficients to describe the characteristics of the channel and floodplain.
- Size, shape, and characteristics of culverts and roadways along the stream reach.
- Energy loss coefficients for flow in the channel and at roadway crossings.

Primary System Study Limits

As discussed with City of Greenville stormwater staff, study limits for the hydraulic evaluation of the primary systems include the segment of Swift Creek from approximately 2,400 feet upstream of Thomas Langston Road crossing at the upstream end to its confluence with an unnamed tributary to Swift Creek (referred to as SCUT1); Swift Creek UT1 from approximately 650 feet upstream of Thomas Langston Road crossing at the upstream end to its confluence with Swift Creek at the downstream end; and Gum Swamp from to approximately 1,600 feet upstream of the Frog Level Road crossing at the upstream end to approximately 1,500 feet upstream of its confluence with Swift Creek at the downstream end.

APPENDIX B

HYDRAULIC ANALYSIS

Stormwater Inventory

For the Swift Creek Watershed Master Plan, stormwater utility infrastructure throughout the watershed was collected by WK Dickson personnel to compile a Geographic Information System (GIS) stormwater inventory database for the City. This was accomplished by using Global Positioning Systems (GPS) as the primary means of data capture. WK Dickson employed survey grade GPS to locate the x, y, and z coordinates of each visible stormwater system structure and conventional surveying techniques to obtain other attributes including but not limited to size, material, slope, and length. Additionally, attributes were also collected for select streams and open channel. Data was obtained for those streams and open channels required to complete connectivity for modeling purposes. The data was collected using horizontal datum NAD 1983 and vertical datum NAVD 1988.

Attributes collected as part of the inventory were used to populate the various models. Field visits and digital photographs for each structure and channel were used to estimate the roughness coefficients and energy loss coefficients. The topographic data used for the Swift Creek Watershed Master Plan was the State of North Carolina's LiDAR data.

Cross Sections

Cross sections utilized in the HEC-RAS model were based on the existing FEMA cross sections (where available). These surveyed cross sections were augmented with additional cross sections surveyed by WK Dickson. The surveyed cross section points were then merged with the digital elevation model based on the LiDAR data. Cross sections were located perpendicular to the flow and at intervals along the stream to characterize the flow capacity of the channel and floodplain for the primary system. Along stream reaches where the shape, size, and geometry of the cross-section are varying, cross sections were cut at closer intervals than for reaches having little change in channel characteristic. Additional sections were cut as required by the HEC-RAS program to sufficiently model structures such as culverts.

Surveyed cross sections are identified by station number, which for the HEC-RAS model, refers to the approximate linear distance upstream from a reference point on the main channel or tributary reach. The cross sections depict the locations of cut sections from field topographic surveys. Similarly, the cross section at each road crossing represents the top-of-road cross section. The cross sections just upstream and just downstream of highest point of roadway (commonly referred to as the weir) represent the locations of the upstream and downstream faces, respectively, of the bridge or culvert in an area not impacted by roadway fill.

APPENDIX B

HYDRAULIC ANALYSIS

Roughness Coefficients

Manning's roughness coefficients, or 'n' values, represent the resistance to flow and influence the flow capacity of channels and floodplains. The HEC-RAS model uses these coefficients to compute friction loss longitudinally in the channel and floodplain. The roughness value is a function of the type and density of the vegetation, channel bottom and stream bank material, degree of channel meandering, and depth of flow.

Roughness coefficients were determined for all stream reaches for which hydraulic analyses were performed. The "horizontal variation in n-values" option was enabled to allow for correct modeling of the widely varied surfaces on a given cross-section. The right or left bank of the stream is referenced facing downstream. Roughness coefficients used in this study are listed in Table B-2.

Table B-2: Roughness Coefficients

| Location | Range of 'n' values |
|----------------|---------------------|
| Main Channel | 0.04 - 0.06 |
| Left Overbank | 0.045 - 0.15 |
| Right Overbank | 0.06- 0.15 |

All roughness coefficients were estimated through field observation and by referencing standard engineering manuals.

Culvert and Roadway Data

Culverts generally have different characteristics than the channel and floodplains away from roadway crossings. Often culverts constrict flood flows in the channel and floodplain, which may create backwater effects upstream of the structure. The constriction can produce increased velocities and result in localized scour.

For culvert analysis, the HEC-RAS model utilizes the concepts of "inlet" control and "outlet" control to simplify complicated culvert hydraulics. Inlet control flow occurs when the flow carrying capacity of the culvert entrance is less than the flow capacity of the culvert barrel. Outlet control flow occurs when the culvert carrying capacity is limited by downstream conditions or by the flow capacity of the culvert barrel.

During inlet control computations, the culvert inlet acts as either a weir or an orifice, and the resulting headwater is computed. The equations used by HEC-RAS are the same as those developed by the Federal Highway Administration during extensive laboratory testing, which describe the inlet control headwater under various conditions.

For outlet control flow conditions, the required headwater is computed considering various conditions. For culverts flowing full, a form of the Bernoulli Equation, which considers

APPENDIX B

HYDRAULIC ANALYSIS

friction losses, entrance losses and exit losses is utilized. Friction losses are based on Manning's equation. Entrance losses are computed as a coefficient times the velocity head in the culvert at the upstream end. Exit losses are computed as a coefficient times the change in velocity head from just inside the culvert (at the downstream end) to outside the culvert.

When the culvert is not flowing full, the direct step backwater procedure is used to calculate the profile through the culvert up to the culvert inlet. An entrance loss is then computed and added to the energy inside the culvert to obtain the upstream headwater. Culvert input data for the HEC-RAS model include:

- Shape and dimensions of the structure openings;
- Culvert length;
- Entrance loss coefficient, exit loss coefficient and coefficient of discharge for weir flow during roadway overtopping;
- Upstream and downstream invert elevations;
- Federal Highway Administration chart number for the culvert type;
- Top-of-road elevations to describe the weir during roadway overtopping and the weir crest length; and
- Four cross sections are required; one cross section sufficiently downstream of the culvert that flow is not affected by the culvert, one at the downstream end of the culvert, one at the upstream end of the culvert, and one located far enough upstream that the culvert has no effect on flow.

Energy Loss Coefficients

Contraction and expansion of flow produces energy losses caused by the transition. The magnitude of these losses is related to the velocity and the estimated loss coefficient. Where the transitions are gradual, the losses are small. At abrupt changes in cross-sectional area, the losses are higher. Energy losses resulting from expansion are greater than losses associated with contraction. Energy loss coefficients used for the Swift Creek Watershed hydraulic models are presented in Table B-3.

Table B-3: Energy Loss Coefficients

| Type of Transition | Expansion | Contraction |
|--------------------|-----------|-------------|
| None | 0 | 0 |
| Gradual | 0.3 | 0.1 |
| Culvert sections | 0.5 | 0.3 |

APPENDIX B

HYDRAULIC ANALYSIS

Starting Water Surface Elevation

The starting water surface elevations for the Swift Creek, SCUT1, and Gum Swamp HEC-RAS models were calculated using the slope-area method, which is based on normal depth. The calculated slopes are as follows:

- 0.003 feet/feet for Swift Creek Main Branch
- 0.004 feet/feet for Swift Creek UT1
- 0.0026 for feet/feet for Gum Swamp

Model Run Descriptions and Assumptions

The HEC-RAS model was used to compute flood elevations at each cross-section for the Swift Creek, SCUT1, and Gum Swamp Primary Systems for the 2-, 10-, 25-, 50- and 100-year floods. A hard copy of the HEC-RAS input and output is included in Appendix H, while a digital copy of the input and output is located on the CD in Appendix J.

The hydraulic analysis for this study is based only on the condition of unobstructed flow. Therefore, flood elevations shown on the profiles are considered valid only if hydraulic structures remain unobstructed and do not fail. Flood elevations may be raised by debris blockage of the culvert, channel, or floodplain.

Model Validation

Efforts were made to verify the models for various storm events. Feedback obtained from the questionnaires was reviewed for relevant information that could be used to verify the model. The comments and responses received were not specific enough to verify the model. Likewise, the information received during the public meetings was not useful for the purposes of verifying the models. The City Staff was able to provide some feedback that was useful during the model validation process.

During the validation process, the flows and water surface elevations initially calculated were determined to be significantly higher than the FEMA flow and base flood elevations. Furthermore, the results from the initial existing conditions model were not aligned with some of the feedback received from the City. The flows were calibrated to get results to more closely match FEMA flows, USGS Regional Regression flows, and City feedback.

Open Channel Systems and Roadway Flooding

Six (6) roadway crossings were analyzed for flooding potential in the Swift Creek Watershed Master Plan. All roadway crossings that were analyzed in this study are listed in Tables B-4a-B-4c along with the minimum top-of-road elevations and the 2-, 10-, 25-, 50- and 100-year flood elevations at the crossing for existing and proposed conditions.

APPENDIX B

HYDRAULIC ANALYSIS

Table B-4a: Overtopping Analysis of Roadway Crossings – Existing Conditions

| Location | Minimum Elevation at Top of Road (feet NAVD) | Desired Level of Service (Year) | Calculated Water Surface Elevations (feet NAVD) | | | | |
|---------------------------------|--|---------------------------------|---|---------------|---------------|---------------|----------------|

APPENDIX B

HYDRAULIC ANALYSIS

SWMM

SWMM is a dynamic rainfall-runoff model capable of modeling the hydrologic response of a watershed and hydraulic routing throughout a stormwater conveyance system. The model calculates the effect of backwater, flat or negative slopes, energy losses, and minor headlosses associated with bends, entrances and exits.

Input data for the EPA SWMM (hydraulics) computer model include the following:

- Conveyance pipes including structure inverts, pipe sizes and lengths;
- Open channel cross section geometries;
- Roughness coefficients for pipes and channels;
- Energy loss coefficients for flow in the pipes and channels;
- Storage rating curves; and
- Overland flow characteristics.

SWMM provides an accurate evaluation of the existing and proposed conditions because it combines hydrology and hydraulics while accounting for the routing effects of the channel and overbank storage areas. Because hydrology and hydraulics are combined, changes to peak flows or water surface elevations resulting from proposed modifications to the existing channels or culverts are calculated in the model in one step. Additionally, changes to flows from proposed pipes and channel improvements are seen both upstream and downstream, reducing the potential for a stormwater system having increased flooding downstream.

Energy Loss Coefficients

Contraction and expansion of flow produces energy losses caused by the transition. The magnitude of these losses is related to the velocity and the estimated loss coefficient. Where the transitions are gradual, the losses are small. At abrupt changes in cross-sectional area, the losses are higher. Energy losses resulting from expansion are greater than losses associated with contraction. Energy loss coefficients used for the hydraulic SWMM models are presented in Table B-5 below:

Table B-5: Energy Loss Coefficients for SWMM Models

| Type of Transition | Expansion | Contraction |
|--------------------|-----------|--------------------------------|
| None | 0 | 0 |
| Manhole/Inlet | 0.7 | 0.5 |
| Open Channel | 1 | 0.5-Headwall/ 0.9 - Projecting |

APPENDIX B

HYDRAULIC ANALYSIS

Additional energy losses for structures having bends were divided between the two joining pipes. The bend losses used for this project are based on NCDOT values, and are shown below in Table B-6.

Table B-6: Bend Loss Coefficients

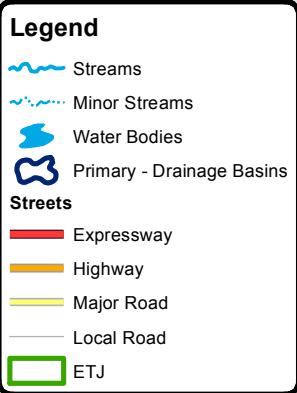

| Angle (°) | Loss Coefficient | Angle (°) | Loss Coefficient |
|-----------|------------------|-----------|------------------|
| 90 | 0.70 | 40 | 0.38 |
| 80 | 0.66 | 30 | 0.28 |
| 70 | 0.61 | 25 | 0.22 |
| 60 | 0.55 | 20 | 0.16 |

GREENVILLE WATERSHED MASTER PLANS QUESTIONNAIRE

The City of Greenville's Stormwater Management Program is conducting a citywide study to identify flooding, erosion, and water quality concerns. Your answers will help us target our efforts. Please take this brief survey to let us know what you are experiencing. Thank you for your participation!

1. Have you ever experienced flooding on your property during a (non-Hurricane) storm? Yes No
If yes, please provide the address where this flooding is occurring.

-
2. If yes, which of the following would apply and what is the frequency?

- Water in storage building _____
 Water on air condition units _____
 Water in crawl space _____
 Water up to, or in the living space _____
 Yard flooding from stream/ditch _____
 Yard flooding from street runoff _____
 Yard flooding from adjacent property _____

| FREQUENCY |
|----------------------------|
| A Less than once a year |
| B Once a year |
| C 2-3 times a year |
| D More than 3 times a year |

3. List dates, locations, and depth of water (*ex: On May 10, 2014, at my mailbox it was 2 feet deep*)
-
-
-

4. Have you ever noticed flooded streets in your neighborhood? Yes No
If yes, tell us when, the locations, and depth of water.
-
-

5. Has flooding increased on your property due to any changes on nearby properties or drainage systems? If yes, what were those changes and the approximate timeframe?

- Yes No
-

6. Have you had any erosion on your property associated with a stream or drainage ditch? Yes No

7. If yes, which of the following are impacted or threatened by erosion Street Yard
 Building/House Fence
 Other _____
-

8. Are you aware that the City of Greenville is currently analyzing and looking for possible solutions to flooding, erosion, and water quality issues throughout the City with a watershed master planning process?
 Yes No

9. If a cost-sharing program was made available along with training, would you be willing to install a project such as a rain garden, cistern, backyard wetland, etc. to help improve water quality in your area?
 Yes No Maybe

10. Are you aware of how the City of Greenville currently spends or utilizes its stormwater utility fee?

Yes No

11. In what ways should the City of Greenville utilize funds to address excessive stormwater runoff, erosion and flooding issues throughout the City? (Check all that apply)

Examples include the following:

- Develop cost-sharing program for installation of projects to reduce stormwater flows
- Develop incentives for replanting areas adjacent to streams
- Construct and maintain regional detention facilities on public properties
- Construct and maintain water quality facilities on public properties
- Stream restoration
- Buyout of flood prone properties
- Other _____

12. Is there anything else you would like for us to know about water quality issues in your area?

May we contact you if we need additional information about flooding and erosion in your area?

Name: _____

Property Address: _____

Primary Residence or Business (if different from Property Address): _____

Phone # (if needed for a response by the City): _____

How long have you been at this location?: _____

Swift Creek Watershed

Division of Stormwater Management

November 3, 2014

Watershed Master Plan Public Meeting

Location: South Central High School

City of Greenville and Consultant Attendees

| | |
|---|------------------------------|
| Lisa Kirby, Project Manager, City of Greenville | Tom Murray, W.K. Dickson |
| Amanda Boone, City of Greenville | Stefani Barlow, W.K. Dickson |
| Victor Long, City of Greenville | Scott Sigmon, W.K. Dickson |
| Marla Hill, PEQ | Inga Kennedy, PEQ |

Meeting Summary

1. Welcome and Purpose of Meeting

- Residents of Greenville's Swift Creek watershed were invited to learn more about the Watershed Master Plan process and to give their input on stormwater issues and challenges they have experienced.
- The meeting began with an open house where attendees could view watershed maps to mark the location of their property, identify areas of flooding and other stormwater issues, and speak with staff and consultants of the City's Stormwater Division about their problems and observations.
- Attendees were then invited to hear a short presentation on the Watershed Master Plan. Project manager Lisa Kirby explained the overall purpose of the master planning process and then invited consultant Tom Murray of W.K. Dickson to describe the findings to date from the field assessment of the watershed. Inga Kennedy of PEQ shared information about the City's public involvement commitment and activities. Lisa Kirby ended the presentation with a description of next steps and then the open house resumed.

2. Questions/Comments by Participants

- Observed city workers overcutting and killing vegetation around city-maintained ditches
- Ditch along the street floods, fills up and could one day overflow onto the highway; also large holes are developing in ditches and getting larger. Could the street be in danger of collapsing?

3. Participant Feedback at Stations

- 3904 Frog Level Road – Faye Barefoot
 - Erosion in the back
 - Water has come up to the air conditioning unit

Find yourself in good company

- Too shallow – could this be deeper or wider?
- 3903 Frog Level Road (and lot beside) – Della Harrell
 - Erosion on the road front
 - Sinkholes in roadside swale
 - Swales fill up and flood the edge of the travel lane
- 3400 Saybrook Ct – Charles Klahn
 - City maintained walking area around pond is mowed too closely and grasses in the swale die
- 745 Seneca Ct – Mike Howell
 - Debris clogging culvert from drainage area from Masters Lane and Nicklaus Drive

| | | | | Design, Administration, Fiscal and Legal (30% of Construction Costs) | 162,900.00 |
| | | | | Total Opinion of Project Cost | \$ 705,900.00 |

* Cost for comprehensive grading includes roadway excavation, saw cutting, compaction of select material, geotechnical recommendations, home owner coordination, tree and structure protection, structure removal and disposal, shoring, and culvert excavation.

** Cost for utility conflicts includes all utilities that need to be moved including sanitary sewer and potable water lines. Additional survey may be required to locate pressurized utilities.

The Engineer's opinions of probable construction costs are made on the basis of the Engineer's experience and qualifications and represent the Engineer's best judgment as a professional generally familiar with the construction industry. Since the Engineer has no control over the cost of labor, materials, equipment, or services furnished by others; over the contractors methods of determining prices; or over competitive bidding or marketing conditions, the Engineer's cannot and does not guarantee that proposal, bids or actual construction costs will not vary from opinions of probable construction costs prepared by the Engineer.

APPENDIX I

BMP CONCEPTUAL DESIGN

Water Quality Wetland - Dana Brooke

Project: City of Greenville - Swift Creek Watershed Master Plan
 Prepared by: SMB
 Checked by: TLM
 Date: 10/26/2015

DRAINAGE AREA INPUT PARAMETERS

| | | | |
|---|-----------------|-------------------|------------|
| Water Quality Event (in) | 1.00 | | Input |
| | Pervious | Impervious | |
| Drainage Area (sq ft) | 4,318,468 | 1,439,489 | Input |
| Sub-basin CN | 74 | 93 | Input |
| S (in) | 3.51 | 0.75 | Calculated |
| R/O (in) | 0.02 | 0.45 | Calculated |
| Sub-basin WQ Volume (sf*in) | 100160 | 648326 | Calculated |
| Sub-basin WQ Volume (cf) | 8347 | 54027 | Calculated |
| | | | |
| Summary Calculations | | | |
| Total Watershed area (sq ft) | 5,757,957 | | Calculated |
| Total Watershed area (acres) | 132.18 | | Calculated |
| Total WQ Runoff Volume (sf*in) | 748,486 | | Calculated |
| Total WQ Runoff Volume (cf) | 62,374 | | Calculated |
| Peak Flow Rate, cfs | 93.55 | | Calculated |
| Pipe Diameter, ft | 37.83 | 42" | Calculated |
| | | | |
| Surface area of wetland | | | |
| Average depth of water (in) | 8 | | Input |
| Surface area of wetland (sf) | 93,561 | | Calculated |
| Surface area of wetland (ac) | 2.15 | | Calculated |
| Surface area of wetland, available (sf) | 94,000 | | Input |
| Surface area of wetland, available (ac) | 2.22 | | Input |

WATERSHED SUMMARY Ver2.0

| REGION: TOTAL DEVELOPMENT AREA (ft ²): | Coastal 286,189 | | |
|---|----------------------------|-----------------------------|--------------------------|
| | Pre-Development Conditions | Post-Development Conditions | Post-Development w/ BMPs |
| Percent Impervious (%) | 40.0% | 42.3% | 42.3% |
| Annual Runoff Volume (c.f.) | 475,829 | 499,660 | 100,197 |
| Total Nitrogen EMC (mg/L) | 1.52 | 1.50 | 1.22 |
| Total Nitrogen Loading (lb/ac/yr) | 6.88 | 7.10 | 1.16 |
| Total Phosphorus EMC (mg/L) | 0.53 | 0.57 | 0.31 |
| Total Phosphorus Loading (lb/ac/yr) | 2.37 | 2.40 | 0.30 |

Percent Difference Between:

| | Pre-Dev. & Post-Dev. without BMPs | Pre-Development & Post-Development with BMPs | Post-Dev without BMPs & Post-Dev with BMPs |
|-------------------------------------|-----------------------------------|--|--|
| Percent Impervious (%) | 2% | 2% | 0% |
| Annual Runoff Volume (c.f.) | 5% | .79% | -.80% |
| Total Nitrogen EMC (mg/L) | -2% | -20% | -.18% |
| Total Nitrogen Loading (lb/ac/yr) | 3% | .83% | -.84% |
| Total Phosphorus EMC (mg/L) | 9% | -40% | -.45% |
| Total Phosphorus Loading (lb/ac/yr) | 1% | .87% | -.88% |

*Negative percent difference values indicate a decrease in runoff volume, pollutant concentration or pollutant loading. Positive values indicate an increase.

BMP SUMMARY Ver2.0

BMP VOLUME REDUCTIONS/EFFLUENT CONCENTRATIONS

| | Volume Reduction (%) | TN Effluent Concen. (mg/L) | TP Effluent Concen. (mg/L) |
|---------------------------------|----------------------|----------------------------|----------------------------|
| BioRetention with IWS | 80% | 0.95 | 0.12 |
| | 50% | 1.00 | 0.12 |
| Dry Detention Pond | 10% | 1.20 | 0.20 |
| Grassed Swale | 10% | 1.21 | 0.26 |
| Green Roof | 50% | 1.08 | 0.15 |
| Level Spdr, Filter Strip | 50% | 1.20 | 0.15 |
| Permeable Pavement* | 60% | 1.44 | 0.39 |
| Sand Filter | 5% | 0.92 | 0.14 |
| Water Harvesting | user defined | 1.08 | 0.15 |
| Wet Detention Pond | 15% | 1.01 | 0.11 |
| Wetland | 25% | 1.08 | 0.12 |

*if treating commercial parking lot, TP effluent concentration = 0.16 mg/L

CHANNEL STABILITY ASSESSMENT FORM

| Stability Indicator | Excellent (1 - 3) | Good (4 - 6) | Fair (7 - 9) | Poor (10 - 12) | Score |
|--|--|--|---|--|-------|
| 1. Watershed and flood plain activity and characteristics | Stable, forested, undisturbed watershed | Occasional minor disturbances in the watershed, including cattle activity (grazing and/or access to stream), construction, logging, or other minor deforestation. Limited agricultural activities | Frequent disturbances in the watershed, including cattle activity, landslides, channel sand or gravel mining, logging, farming, or construction of buildings, roads, or other infrastructure. Urbanization over significant portion of watershed | Continual disturbances in the watershed. Significant cattle activity, landslides, channel sand or gravel mining, logging, farming, or construction of buildings, roads, or other infrastructure. Highly urbanized or rapidly urbanizing watershed | |
| 2. Flow habit | Perennial stream with no flashy behavior | Perennial stream or ephemeral first-order stream with slightly increased rate of flooding | Perennial or intermittent stream with flashy behavior | Extremely flashy; flash floods prevalent mode of discharge; ephemeral stream other than first-order stream | |
| 3. Channel pattern | Straight to meandering with low radius of curvature; primarily suspended load | Meandering, moderate radius of curvature; mix of suspended and bed loads; well-maintained engineered channel | Meandering with some braiding; tortuous meandering; primarily bed load; poorly maintained engineered channel | Braided; primarily bed load; engineered channel that is maintained | |
| 3. Channel pattern (revised) | No evidence of channelization. Meandering, stable channel or straight (step-pool system, narrow valley), stable channel. | Appears to have previously been channelized. Stream is relatively stable. Channel has some meanders due to previous channel adjustment. | Appears to have previously been channelized. Stream is actively adjusting (meandering); localized areas of instability and/or erosion around bends. Straightened, stable channel. | Appears to have previously been channelized. Stream is actively adjusting (laterally and/or vertically) with few bends. Straight, unstable reach. | |
| 4. Entrenchment/ channel confinement | Active flood plain exists at top of banks; no sign of undercutting infrastructure; no levees | Active flood plain abandoned, but is currently rebuilding; minimal channel confinement; infrastructure not exposed; levees are low and set well back from the river | Moderate confinement in valley or channel walls; some exposure of infrastructure; terraces exist; flood plain abandoned; levees are moderate in size and have minimal setback from the river | Knickpoints visible downstream; exposed water lines or other infrastructure; channel-width-to-top-of-banks ration small; deeply confined; no active flood plain; levees are high and along the channel edge | |
| 5. Bed material Fs = approximate portion of sand in the bed | Assorted sized tightly packed, overlapping, and possibly imbricated. Most material > 4 mm. Fs < 20% | Moderately packed with some overlapping. Very small amounts of material < 4 mm. 20 < Fs < 50% | Loose assortment with no apparent overlap. Small to medium amounts of material < 4 mm. 50 < Fs < 70% | Very loose assortment with no packing. Large amounts of material < 4 mm. Fs > 70% | |
| 6. Bar development | For S < 0.02 and w/y > 12, bars are mature, narrow relative to stream width at low flow, well-vegetated, and composed of coarse gravel to cobbles. For S > 0.02 and w/y are < 12, no bars are evident | For S < 0.02 and w/y > 12, bars may have vegetation and/or be composed of coarse gravel to cobbles, but minimal recent growth of bar evident by lack of vegetation on portions of the bar. For S > 0.02 and w/y < 12, no bars are evident | For S < 0.02 and w/y > 12, bar widths tend to be wide and composed of newly deposited coarse sand to small cobbles and/or may be sparsely vegetated. Bars forming for S > 0.02 and w/y < 12 | Bar widths are generally greater than 1/2 the stream width at low flow. Bars are composed of extensive deposits of fine particles up to coarse gravel with little to no vegetation. No bars for S < 0.02 and w/y > 12 | |
| 7. Obstructions, including bedrock outcrops, armor layer, LWD jams, grade control, bridge bed paving, revetments, dikes or vanes, riprap | Rare or not present | Occasional, causing cross currents and minor bank and bottom erosion | Moderately frequent and occasionally unstable obstructions, cause noticeable erosion of the channel. Considerable sediment accumulation behind obstructions | Frequent and often unstable, causing a continual shift of sediment and flow. Traps are easily filled, causing channel to migrate and/or widen | |
| 8. Bank soil texture and coherence | Clay and silty clay; cohesive material | Clay loam to sandy clay loam; minor amounts of noncohesive or unconsolidated mixtures; layers may exist, but are cohesive materials | Sandy clay to sandy loam; unconsolidated mixtures of glacial or other materials; small layers and lenses of noncohesive or unconsolidated mixtures | Loamy sand to sand; noncohesive material; unconsolidated mixtures of glacial or other materials; layers of lenses that include noncohesive sands and gravels | |
| 9. Average bank slope angle (where 90° is a vertical bank) | Bank slopes < 3H:1V (18°) for noncohesive or unconsolidated materials to < 1:1 (45°) in clays on both sides | Bank slopes up to 2H:1V (27°) in noncohesive or unconsolidated materials to 0.8:1 (50°) in clays on one or occasionally both banks | Bank slopes to 1H:1V (45°) in noncohesive or unconsolidated materials to 0.6:1 (60°) in clays common on one or both banks | Bank slopes over 45° in noncohesive or unconsolidated materials or over 60° in clays common on one or both banks | |
| 10. Vegetative or engineered bank protection | Wide band of woody vegetation with at least 90% density and cover. Primarily hard wood, leafy, deciduous trees with mature, healthy, and diverse vegetation located on the bank. Woody vegetation oriented vertically. In absence of vegetation, both banks are lined or heavily armored | Medium band of woody vegetation with 70-90% plant density and cover. A majority of hard wood, leafy, deciduous trees with maturing, diverse vegetation located on the bank. Woody vegetation oriented 80-90% from horizontal with minimal root exposure. Partial lining or armoring of one or both banks | Small band of woody vegetation with 50-70% plant density and cover. A majority of soft wood, piney, coniferous trees with young or old vegetation lacking in diversity located on or near the top of bank. Woody vegetation oriented at 70-80% from horizontal, often with evident root exposure. No lining of banks, but some armoring may be in place on one bank | Woody vegetation band may vary depending on age and health with less than 50% plant density and cover. Primarily soft wood, piney, coniferous trees with very young, old and dying, and/or monostand vegetation located off of the bank. Woody vegetation oriented at less than 70% from horizontal with extensive root exposure. No lining or armoring of banks | |
| 11. Bank cutting | Little or none evident. Infrequent raw banks, insignificant percentage of total bank | Some intermittently along channel bends and at prominent constrictions. Raw banks comprise minor portion of bank in vertical direction | Significant and frequent on both banks. Raw banks comprise large portion of bank in vertical direction. Root mat overhangs | Almost continuous cuts on both banks, some extending over most of the banks. Undercutting and sod-root overhangs | |
| 12. Mass wasting or bank failure | No or little evidence of potential or very small amounts of mass wasting. Uniform channel width over the entire reach | Evidence of infrequent and/or minor mass wasting. Mostly healed over with vegetation. Relatively constant channel width and minimal scalloping of banks | Evidence of frequent and/or significant occurrences of mass wasting that can be aggravated by higher flows, which may cause undercutting and mass wasting of unstable banks. Channel width quite irregular, and scalloping of banks is evident | Frequent and extensive mass wasting. The potential for bank failure, as evidenced by tension cracks, massive undercuttings, and bank slumping is considerable. Channel width is highly irregular, and banks are scalloped | |
| 13. Upstream distance to bridge from meander impact point and alignment | More than 35 m; bridge is well-aligned with river flow | 20-35 m; bridge is aligned with flow | 10-20 m; bridge is skewed to flow, or flow alignment is otherwise not centered beneath bridge | Less than 10 m; bridge is poorly aligned with flow | |

H = horizontal, V = vertical, Fs = fraction of sand, S = slope, w/y = width-to-depth ratio

*Raw numbers are shown in left side of column and weighted numbers are provided in right side of column. Totals are based on weighted numbers.

| Category | General Description | Score | Evaluation Criteria |
|--|---|------------------|--|
| Public Health and Safety | Evaluates potential impact of flooding on public health and safety. Generally, refers to flooding in and around habitable structures. | 5 3 1 0 | <p>Flood water depth and/or velocity completely surrounds and threatens the structural integrity of habitable structures or vehicles.</p> <p>Finished Floor Flooding Occurs during the design storm.</p> <p>Erosion of stream running parallel to road threatening roadway stability or safety for Secondary</p> <p>Flood water surrounds structure but does not cause imminent danger.</p> <p>Crawl space and HVAC units are flooded.</p> <p>Yard flooding occurs and flood waters are near HVAC, crawl spaces or foundations.</p> <p>Model indicates flooding at nodes on private property or on roads/private property within a residential neighborhood.</p> <p>Minor yard flooding may occur but habitable structure is not directly affected.</p> <p>Model indicates no flooding at nodes on private property.</p> |
| Severity of Street Flooding (City Owned) | Evaluates impact of flood depths to or through an area | 5 3 1 0 | <p>Street spread requirements are not met and are so severe that the street becomes impassable during the design storm or street flooding has spread into private property.</p> <p>Flooding is noted on NCDOT roads as a result spread issues on adjacent city owned street.</p> <p>Roadway overtopping exceeding 6" in depth for Primary Systems.</p> <p>Street spread requirements are not met and the streets are passable only through the center of the street.</p> <p>Flooding noted on collector and local streets.</p> <p>Roadway overtopping 0-6" in depth for Primary Systems</p> <p>Spread requirements exceeded but street flooding is considered minor nuisance for traffic.</p> <p>Spread requirements are met.</p> |
| Cost Effectiveness | Evaluates the benefit/cost of the proposed improvements | 5 3 1 0 | <p>Project benefit ratio is greater than 1.5</p> <p>Stream Stabilization cost <\$400 per linear foot</p> <p>Project benefit ratio is between 0.5 and 1.5</p> <p>Stream Stabilization cost <\$600 per linear foot</p> <p>Project benefit ratio is between 0.075 and 0.5</p> <p>Stream Stabilization cost <\$1,000 per linear foot</p> <p>Project ratio is less than 0.075</p> <p>Stream Stabilization cost >\$1,000 per linear foot</p> |

| Category | General Description | Score | Evaluation Criteria |
|------------------------|--|-------|--|
| Effect of Improvements | Evaluates the number of drainage issues resolved and the number of citizens positively affected | 5 | Multiple major drainage issues are being resolved through the proposed improvements such as street spread and increased drainage capacity. Proposed improvements would resolve major drainage issues for more than 5 properties. |
| | | 3 | Single drainage issue is being resolved and it is considered major. Proposed improvements would resolve drainage issues for 3-5 properties. |
| | | 1 | Single drainage issue is being resolved and it is considered major. Proposed improvements would resolve drainage issues for 2-3 properties. |
| | | 0 | Single drainage issue is being resolved and it is considered minor. Proposed improvements would resolve drainage issue(s) for a single property at most. |
| | | 5 | Provides both water quantity and water quality benefits. Does not use manufactured or proprietary BMP technology. Incorporates some form of green solution such as infiltration, LID, sustainability etc. Is considered a BMP retrofit. |
| Water Quality/Quantity | Evaluates the impact a BMP would have on water quality, water quantity and NPDES Phase II Compliance | 3 | Provides water quality benefits but does not provide water quantity benefit. Is considered a BMP retrofit |
| | | 1 | Improvements will have minimal impacts on water quality and would primarily serve as a demonstration project. Is considered a BMP retrofit. |
| | | 0 | Improvements will have no measurable impact on water quality and would serve only as a demonstration project. |

| Category | General Description | Score | Evaluation Criteria |
|--------------------------------|---|---------------------|--|
| Open Channel - Erosion Control | Evaluates the severity of erosion control issues and impact on water quality | 5 3 1 0 | <p>Severe erosion problems are evident and are contributing significantly to water quality issues.</p> <p>Moderate erosion problems are evident and are contributing to water quality issues.</p> <p>>2,000 Linear feet of floodplain benching with documented erosion.</p> <p>Minor erosion control issues are evident and are contributing to water quality issues.</p> <p><2,000 Linear feet of floodplain benching with documented erosion.</p> <p>Minor erosion control issues are evident and are not contributing to water quality issues in a significant way.</p> |
| Implementation Constraints | Considers potential constraints that may either delay or make the project too difficult to construct. Some examples would include significant permitting issues, high mitigation costs, numerous easement needs, required partnering with other communities, the NCDOT, or railroads. | 5 3 1 | <p>Only minor local or state permits required. Does not involve ACOE, DWQ or FEMA.</p> <p>Proposed improvements can be completed without permanent or temporary easements.</p> <p>Project can proceed independent of other stormwater improvements identified in the master plan.</p> <p>Requires State and Federal permits that are typically easy to obtain such as Nationwide permits, FEMA No Rise etc.</p> <p>Primarily requires temporary easements with only a few permanent easements needed to build the project.</p> <p>Improvements may have limited coordination with other projects such as DOT widening, GUC utility improvements or down stream drainage improvements. Significant delays in the schedule due to this coordination is not anticipated.</p> <p>Project can proceed independent of other stormwater improvements identified in the master plan.</p> <p>Project is self mitigating or requires very minor mitigation.</p> <p>Numerous permits required including federal, state and local agencies. Examples would include an individual permit or FEMA CLOMR/LOMR.</p> <p>Extensive permanent and temporary easements are required.</p> <p>Project can not proceed independent of other stormwater improvements identified in the master plan.</p> <p>Requires floodplain benching.</p> |

| Category | General Description | Score | Evaluation Criteria |
|------------------|---|-------|---|
| Grant Funding | Evaluates the availability and potential to receive grant funding | 5 | <p>Project qualifies for multiple grants.</p> <p>Grant does not require significant match (20% match or less)</p> <p>City does not have an open grant from the agency providing the funding.</p> <p>Project meets all ranking criteria and will score highly in most if not all categories.</p> |
| | | 3 | <p>Project qualifies for only one type of grant funding.</p> <p>Grant requires match between 20% and 50% range.</p> <p>City has an open grant from agency providing the funding.</p> <p>Project meets most if not all of the ranking criteria and will score high in key categories.</p> |
| | | 1 | <p>Project qualifies for only one type of grant funding.</p> <p>Grant requires match equal to or greater than 50%.</p> <p>City has an open grant from agency providing the funding.</p> <p>Project meets some of the ranking criteria and may score high in one or two categories.</p> |
| | | 0 | Project does not qualify for any type of grant funding |
| Constructability | Evaluates relative constructability of the project including site constraints, traffic and neighborhood impacts, and impacts on adjacent property owners. | 5 | <p>Limited to no site constraints.</p> <p>Limited to no utility conflicts.</p> <p>Limited to no impacts on adjacent property owners.</p> <p>Limited to no impacts on traffic or surround neighborhoods.</p> |
| | | 3 | <p>Some site constraints exist but are considered fairly minor.</p> <p>Some utility conflicts exist but are routine and do not require major utility relocation.</p> <p>Some traffic and neighborhood impacts occur but are fairly minor. Examples include temporary lane closures, occasional hauling or traffic detours through adjacent neighborhoods.</p> |
| | | 1 | <p>Site constraints exist and are fairly major.</p> <p>Utility conflicts exist and require rerouting or relocation of existing utilities.</p> <p>Traffic and neighborhood impacts occur and are fairly major. Examples included extended road closures or hauling operations.</p> |

To calculate the project benefit ratio used in evaluating the cost effectiveness, the following steps were taken for each project location:

1. The weighted scores for the Public Health and Safety, Severity of Street Flooding, and Effect of Improvements categories were added together.
2. The sum of the three categories was divided by the total project cost.
3. The quotient was multiplied by a common multiplier, 5,000, to determine the benefit ratio.
4. The value was then assigned a score based on the evaluation criteria shown below for the cost effectiveness criteria.

| Score | Evaluation Criteria |
|--------------|--|
| 5 | Project benefit ratio is greater than 1.5 |
| 3 | Project benefit ratio is between 0.5 and 1.5 |
| 1 | Project benefit ratio is between 0.075 and 0.5 |
| 0 | Project ratio is less than 0.075 |

5. The applicable weighting factor is then applied to the score. The final number obtained is listed in the project prioritization matrix.

| Weight Factor | Criteria |
|----------------------|--|
| 10 | Public Health and Safety |
| | Severity of Street Flooding (Town Owned) |
| | Cost Effectiveness |
| 6 | Effect of Improvements |
| | Water Quality - BMP and Erosion Control |
| | Implementation Constraints |
| | Grant Funding |
| 3 | Construction Impacts |
| | Constructability |

The above table presents the weighting factors that will be applied to the prioritization criteria, with the reason being that some criteria are viewed as more important (i.e. deserve a higher weighting) than others. So each score of each prioritization criteria will be multiplied by the assigned weight factor for that prioritization criteria category as shown in the Priority Matrix.

EXECUTIVE SUMMARY

East Carolina University was awarded an 18-month contract to monitor water quality in the Swift Creek (SC) watershed upstream of NC 102 (37.8 mi²) as part of the City of Greenville's Watershed Master Planning project. The SC watershed was selected because it is currently listed on the 303d list of impaired waters for North Carolina.

The goal of the water quality monitoring program was to determine whether nutrients, pathogens, sediments, or metals are impairing SC, and if so, to locate any potential sources of degradation. Water quality monitoring included sampling stream flow during base and storm flow conditions at least four times at seven locations on SC (1-7), and two outfalls (SC9 & SC10). Two longitudinal surveys of water quality were conducted at 16 locations along SC. Stage and conductivity were recorded continuously at three locations within the watershed as well.

Sampling results were compared with water quality standards or surrogate standards to evaluate whether parameters may be contributing to stream degradation. Exceedance of standards occurred more frequently during storm flow events rather than baseflow events. Total suspended solids (TSS) concentrations exceeded 20 mg/l (North Carolina standard for High Quality Waters) during two storm flow events at nearly all sites on SC, while the turbidity standard (50 NTU) was violated during only one storm (November 24) at five sites, SC3 – SC7. Agricultural land use below the head waters was likely the most significant contributor of sediment loads to SC.

Results for E. coli exceeded EPA recommended levels (528 MPN/100 ml) during only one baseflow event (October 13) at all in-stream sites, while in-stream results from three storms exceeded the standard, primarily upstream of SC6. Similar trends were observed for storm flow concentrations of E. coli, chloride, and organic nitrogen, which could indicate a wastewater source.

Although nutrient concentrations did not exceed existing numeric standards, baseflow nitrate-nitrite concentrations exceeded conservative numeric guidelines set in Florida (0.3 mg/l). Nitrate concentrations steadily increased downstream from headwaters for baseflow and storm flow events. Baseflow concentrations were highest for the winter sampling, likely due to increased agricultural drainage in response to an elevated water table during this time of year. Results of ¹⁵N-NO₃ isotope analyses suggest fertilizer or soil as the primary source of nitrate, although wastewater could not be ruled out due to possible mixing. Of note, baseflow ¹⁵N-NO₃ from SC4 was most enriched, suggesting this was the site most likely to be influenced by wastewater. Additional monitoring and comparison of sewered and septic areas could help to determine wastewater-related N-inputs. In addition, baseflow nitrate concentrations at SC4 were elevated compared to in-stream concentrations at SC3 (upstream) and SC5 (downstream). Efforts to reduce nitrogen along the tributary upstream of SC4 would likely reduce nitrogen and improve water quality along the main stem.

Total dissolved phosphorus concentrations primarily exceeded numeric guidelines from Florida (0.06 mg/l) during one storm event (November 24). Otherwise, baseflow and storm flow concentrations generally increased downstream from head waters, where agricultural land use is more prevalent in the watershed.

None of the metals were found to exceed state standards, as concentrations were below detection limits for copper (10 µg/l) and lead (5 µg/l) and zinc concentrations were less than state standards (50 µg/l).

INTRODUCTION

Study Location

Swift Creek's (SC's) headwaters originate in the Greenville, NC area and the study area extends from its headwaters, down to the Route 102 Bridge at Ayden, NC. The SC watershed (HUC12: 030202020401) is located in the inner Coastal Plain, where the bulk of discharge to streams is from unconfined aquifers (Winner and Coble, 1996). The main stem of SC flows from urbanized headwaters to the south through a mostly agricultural watershed towards the Neuse River. Topographic relief and land cover are shown with the SC watershed boundary in Figures 1 and 2, respectively.

Soils within the SC watershed are mostly poorly drained with fine-loamy texture. Typically the surficial aquifer drains to streams and it is underlain at approximately 10-20 ft. below the surface by the Yorktown confining unit (which overlays the Yorktown aquifer). As much of the SC watershed is or was once used for agricultural production, drainage channels and tile drains serve as collectors of stormwater runoff within the rural catchments. These channels efficiently convey runoff to SC and its tributaries. Historical channelization has also reduced the channel length and increased the channel slope along sections of SC, which has led to incision, lateral erosion and disconnection between the stream channel and its flood plain.

On average, the watershed receives 125 cm (49.3 in.) of rain per year, ranging from a maximum of 15.0 cm (5.89 in.) in August to a low of 7.09 cm (2.79 in.) in November (Holder et al., 2006; Southeast Regional Climate Center, 2009). The mean air temperature is 16.2°C (61.2°F), from a low of -0.39°C (31.3°F) in January to a high of 21.2°C (70.2°F) in July (NCEI, 2015). Elevated evapotranspiration in the summer months can result in reductions in streamflow during this period. On an annual basis, evapotranspiration accounts for approximately 70% of precipitation losses (Sun et al. 2002). Based on previous studies in the region, groundwater inputs to streams are typically lowest during the period of June–November. Total discharge follows this seasonal pattern but may also increase during September due to increased runoff from tropical storms. Typically streamflow is greatest during March and lowest during October. Groundwater is usually the dominant source of streamflow, contributing approximately 60% of annual discharge (O'Driscoll et al. 2010).

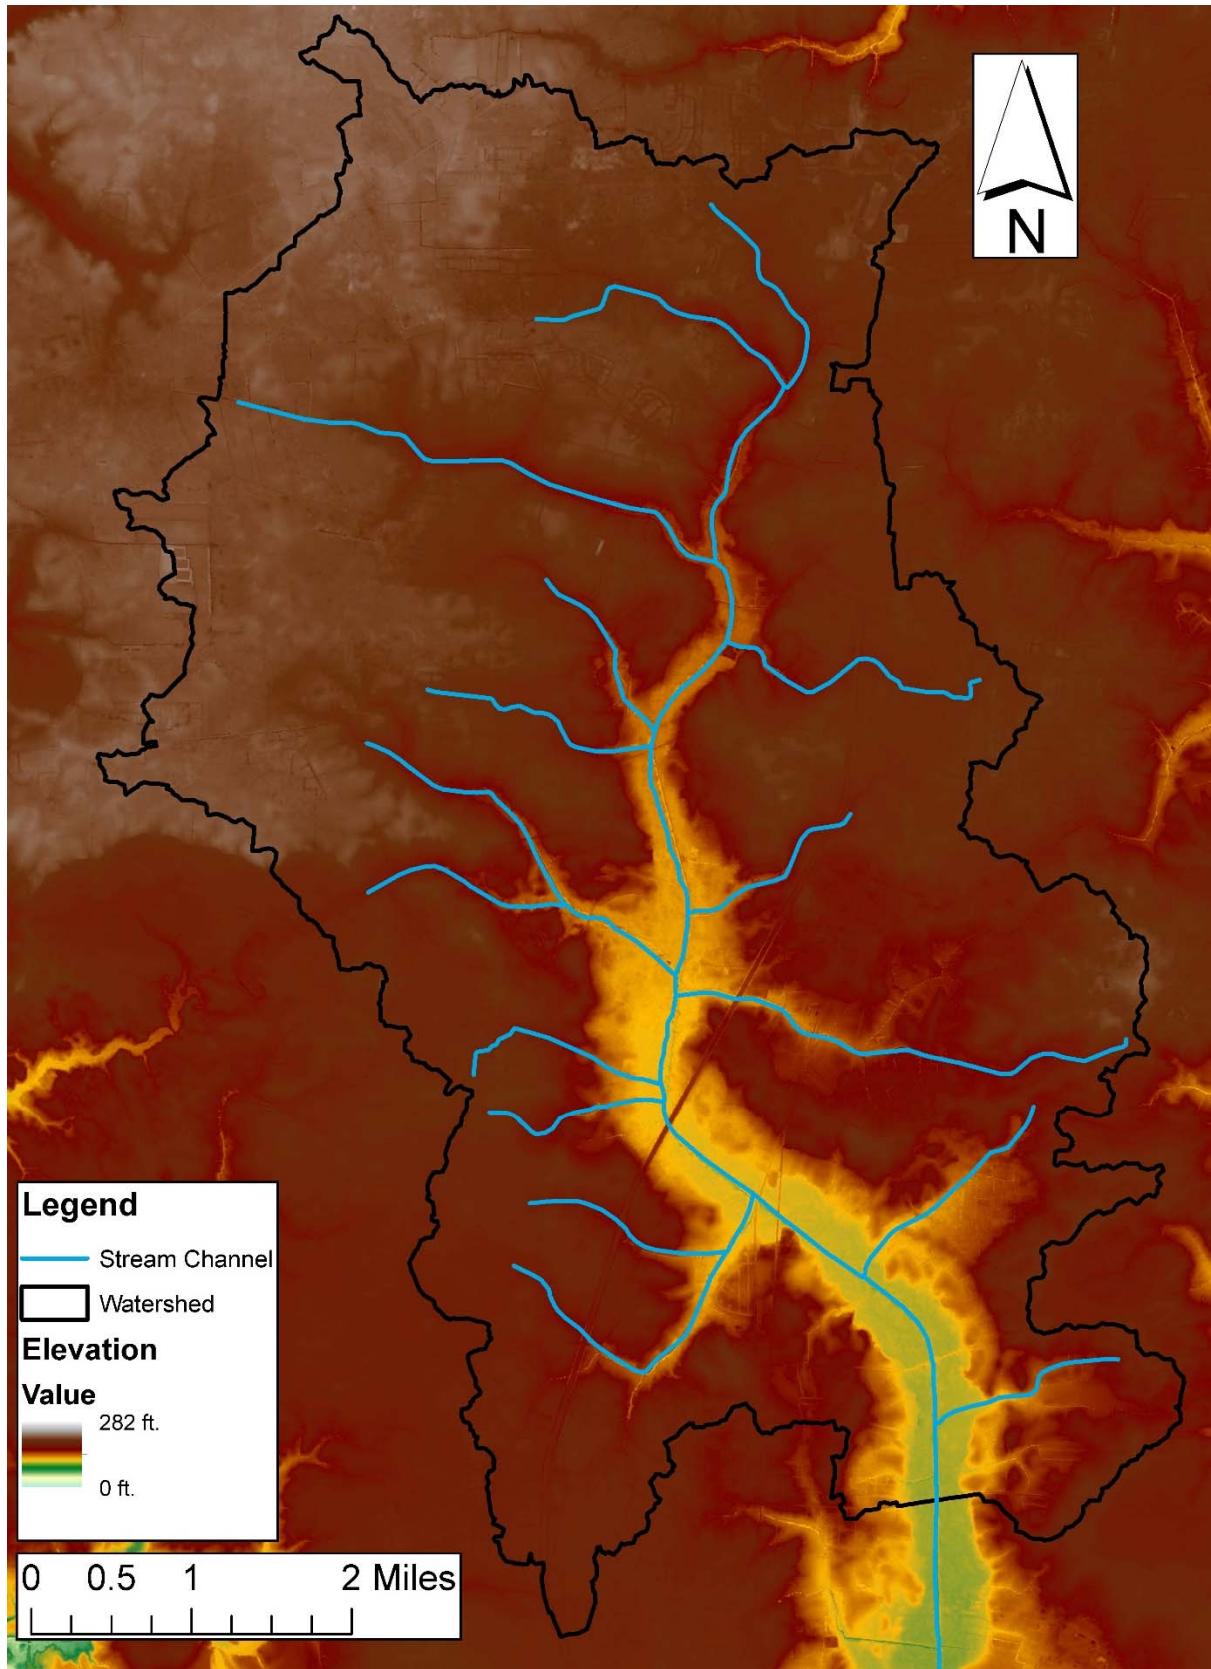

Figure 1. Topography within and around Swift Creek watershed.

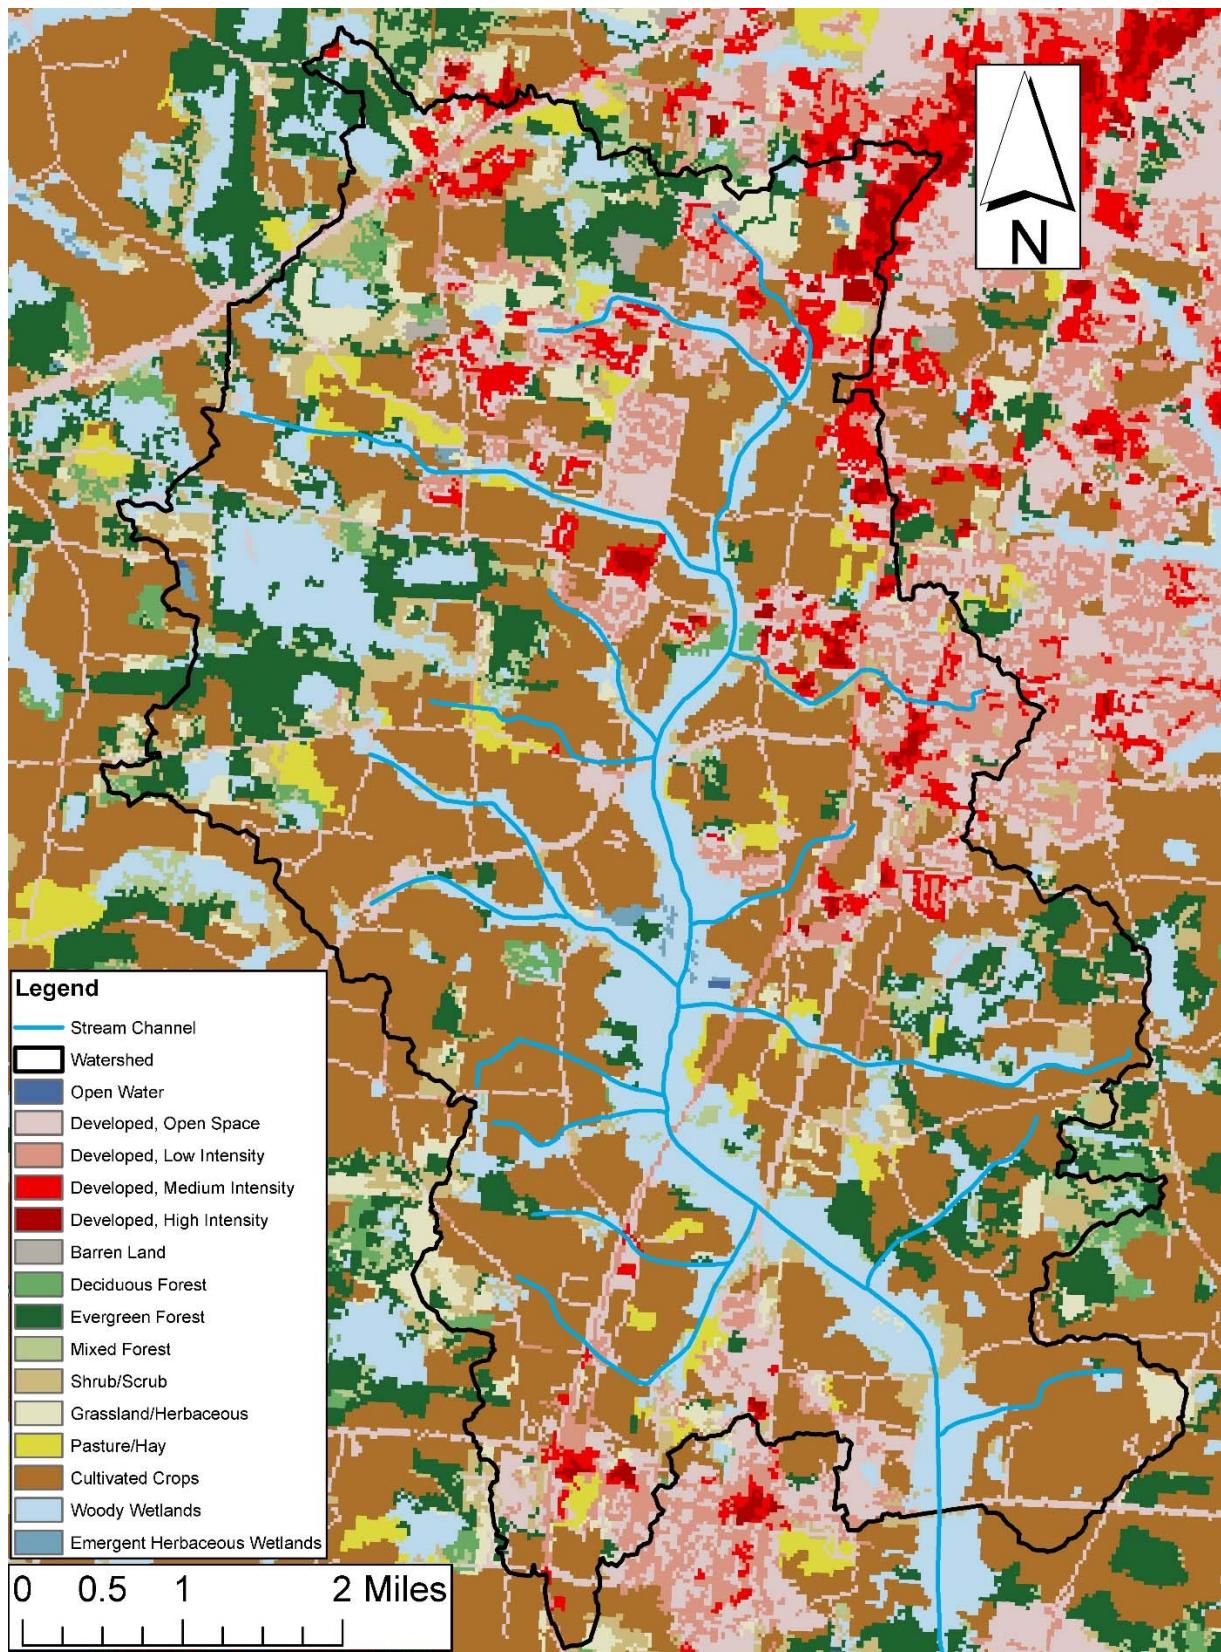

Figure 2. Land cover within and around Swift Creek watershed. Data from National Land Cover Data set.

Current Condition

The North Carolina Department of Environmental Quality (NCDEQ) currently lists Swift Creek as being a Class C surface water, meaning it is protected for secondary recreation (wading, boating, and other types of infrequent, unorganized, or incidental human body contact), fishing, wildlife, fish consumption, aquatic life (propagation, survival, and maintenance of biological integrity), and agriculture. In addition, NCDEQ has applied two supplemental classifications to Swift Creek. The Swamp Waters (Sw) supplemental classification is intended to recognize waters having “low velocities and other natural characteristics which are different from adjacent streams”, such as lower pH, lower dissolved oxygen, and higher temperatures (NCDENR, 2009). The Nutrient Sensitive Waters (NSW) supplemental classification is “intended for waters needing additional nutrient management due to their being subject to excessive growth of microscopic or macroscopic vegetation” and is applied to Swift Creek as a tributary to the Neuse River.

Since 1998, a 19.3 mile stretch of Swift Creek (from its source to 5.3 miles upstream of Clayroot Swamp) has been classified as impaired for not meeting the aquatic life standard due to a poor bioclassification rating for ecological or biological integrity of benthos. This classification does not specify the cause of the condition and may result from individual or multiple environmental factors.

Study Objectives

The goal of the water quality monitoring program was to determine whether nutrients, pathogens, sediments, or metals were contributing to impairment of Swift Creek.

METHODS

Sampling and monitoring plans were developed to evaluate the flow and water quality over time within Swift Creek, upstream of NC 102.

Water Quality Sampling and Measurements

Seven in-stream (SC1-SC7) and two outfall (SC9, SC10) locations were selected for sampling along Swift Creek and its tributaries (Table 1 and Figure 3). Water quality samples and measurements were collected during baseflow and storm flow (or wet weather) events during the study period. These sites were distributed along SC and its tributaries to evaluate water quality throughout the watershed and determine if any section(s) of SC was more affected than others. In addition, baseflow and storm flow samples were collected across seasons to evaluate seasonal fluctuations of water quality.

Samples were collected during four baseflow and four storm flow events. All sites were sampled for each baseflow and storm sampling event. Samples were also collected in coordination with benthic sampling on August 18-21, 2014; when available results were included with those from the other four baseflow events. Seasonal baseflow and storm

flow event dates are listed in Table 2 and occurred approximately during each season between October 2014 and September 2015. Rainfall less than 1.00 in. during 72 hours (3 days) prior to sampling was required for baseflow events. This criterion was supported with monitoring data as storm hydrographs returned to baseflow within 72 hours of precipitation events, except for the largest of rainfall events. In addition, samples were also collected in conjunction with benthic sampling in August 2014 and met the criteria for baseflow sampling.

Table 1. Locations of baseflow and stormwater monitoring sites along Swift Creek, an un-named tributary (SC4), and two outfalls (SC9, SC10).

| Location | Latitude | Longitude | Sampling | Stage Monitoring | Conductivity Monitoring |
|------------|------------------|------------------|----------|------------------|-------------------------|
| SC 1 | 35° 33' 14.52" N | 77° 24' 52.38" W | Y | | |
| SC 2 | 35° 33' 13.62" N | 77° 24' 48.54" W | Y | Y | Y* |
| SC 3 | 35° 32' 44.4" N | 77° 25' 11.1" W | Y | | |
| SC 4 | 35° 32' 36.66" N | 77° 25' 30.24" W | Y | | |
| SC 5 | 35° 32' 17.1" N | 77° 25' 7.92" W | Y | Y | Y |
| SC 6 | 35° 30' 0.06" N | 77° 25' 29.22" W | Y | Y | Y |
| SC 7 | 35° 28' 10.02" N | 77° 24' 1.98" W | Y | | |
| SC 9 | 35° 32' 13.67" N | 77° 25' 7.17" W | Y | | |
| SC 10 | 35° 32' 14.02" N | 77° 25' 7.08" W | Y | | |
| Rain Gauge | 35° 32' 31.2" N | 77° 25' 37.2" W | | | |

*Removed due to burial and operational issues.

Table 2. Sampling dates for baseflows, storm (wet weather) flows, and longitudinal surveys.

| Sampling | Dates |
|----------------------|--|
| Baseflow | 2014: Aug 18-21, Oct 13; 2015: Feb 24, Apr 13, Aug 24 ^a |
| Storm Flow | 2014: Nov 24; 2015: Feb 2, Jul 13, Sep 25 ^{a,b} |
| Longitudinal Surveys | 2015: Apr 13, Aug 24 |

^aSamples for metals analysis collected at SC 1, 3, and 5. ^bSamples for isotope analyses collected at all sampling sites.

The target threshold for storm flow sampling was set at 0.50 in. of rainfall within a three hour period. Only the July 13 event did not meet this criterion, when approximately 0.34 in. fell during a three hour period. Storm flow samples were collected by first flush sampling on November 24, 2014, and February 2, 2015. All other base flow and storm flow samples were collected via direct grab sampling. For grab sampling, bottles were rinsed in stream water three times prior to collecting each sample. Sample bottles were labeled with identification numbers and immediately put on ice after collection.

TSS and Nutrient Analyses

For each sampling event, samples were collected in high density polyethylene (HDPE) bottles, for water quality analyses at the Environmental Research Lab. Samples were filtered on same day as they were collected. These analyses included Total Suspended Solids (TSS), nitrogen species (Ammonia (NH₄), Nitrate+Nitrite (NO₂₊₃), Total Dissolved

Nitrogen (TDN)), phosphate (PO_4), Dissolved Organic Carbon (DOC), and chloride (Cl). Nutrient samples were frozen until analyses were performed.

Bacterial Analyses

Samples for bacteria analyses were also collected for each sampling event. Analyses were completed at the ECU Environmental Health Sciences Water Laboratory. Bacteria samples were collected in sealed polyethylene terephthalate (PET) bottles and were analyzed for total coliform and *E. coli*. Samples were diluted (dilution factors of 10:100) before preparation and incubation because of anticipated high concentrations. Samples were prepared and incubated within 6 hours of collection. Samples were analyzed for total coliform and *E. coli* using the IDEXX *Colilert* substrate with *Quantitray 2000* for most probable number (MPN) determination. The sample trays were incubated at 35°C for 24 hours and wells which illuminated yellow under laboratory lights were recorded as positives for total coliform. Tray wells that illuminated under a black light were recorded as positives for *E. coli*.

Metals Analyses

Samples were collected of baseflow on August 24, 2015 and storm flow on September 25, 2015 for metals analyses (Copper (Cu), Lead (Pb), and Zinc (Zn)) at SC 1, 3, and 5. The sample analyses were performed by Environment One Laboratories, Inc. in Greenville, NC using EPA method 200.7 for Cu and Zn, and Standard Method 3113B-04 for Pb.

Isotope Analyses

Storm flow samples were collected for isotope analyses on September 25, 2015. These samples will be analyzed at the University of California at Davis for N^{15} and O^{18} in NO_3 . These data will provide information on the sources of nitrogen entering SC. Samples were sent to UC Davis in December.

In Stream Measurements

In stream water quality readings for temperature, specific conductivity, conductivity, dissolved oxygen concentration, and pH were measured using calibrated YSI 556 MPS sensors. Turbidity was measured using a HACH 2020we turbidimeter.

At each site, field sampling sheets were completed to record field meter readings, sample identification numbers, location of any photos, arrival and departure time, and relevant other notes. Field sheets were scanned and stored electronically.

Monitoring Sites

Three sites (SC 2, SC 5, and SC 6) were also selected as water level monitoring sites. At each monitoring site, Onset HOBO Water Level Data Loggers (U20-001 or U20L-01) were deployed to record and collect pressure every 30 minutes. Readings were corrected for atmospheric pressure fluctuations to estimate water level records. Staff gauges were also installed at each location. Stage was monitored at these sites during the period of January 9 through October 14, 2015.

Discharge was calculated from stage records using stage-discharge rating curves. Stage and discharge were measured on nine occasions during the monitoring period. Flow meters were used to measure the flow velocity across the stream cross-section. The cross-section area was estimated by measuring equally spaced depths across the channel width. Discharge was calculated as the product of the average flow velocity and cross-sectional area. Staff gauge water levels were also recorded and used to correct water level records as necessary.

The stage-discharge rating curves took the form of $Q = C*(s^n)$, where Q is the discharge (cfs), s is the stage (ft.), and C and n were values determined by linear regression. Rating curves were developed by linear regression of discharge and stage on log-log plots. Rating curve equations are listed in the Appendix.

These three sites were also instrumented with conductivity loggers. Conductivity can be used in place of direct measurement of other water quality parameters and at a much lower cost to record changes in water quality over time. Each site was instrumented with an Onset HOBO Fresh Water Conductivity Data Logger (U24-001) and set to record every 30 minutes.

Longitudinal Surveys

Two longitudinal surveys were conducted (April 15 and August 24) during base flow conditions along the main stem and tributaries of SC. These surveys were conducted to provide a finer spatial resolution of water quality variation along SC. Any significant changes along SC could detect where sources of water quality impairment may be entering. A total of 24 sites, including the 5 sampling sites and 11 additional sites, were included in these surveys (Figure 3). At each site, a YSI 556 MPS was used to measure temperature, specific conductivity, dissolved oxygen, and pH, while turbidity was measured using a LaMotte 2020we turbidimeter. At each site, field sampling sheets were completed to record field meter readings, sample identification numbers, location of any photos, arrival and departure time, and relevant other notes. Field sheets were scanned and stored electronically.

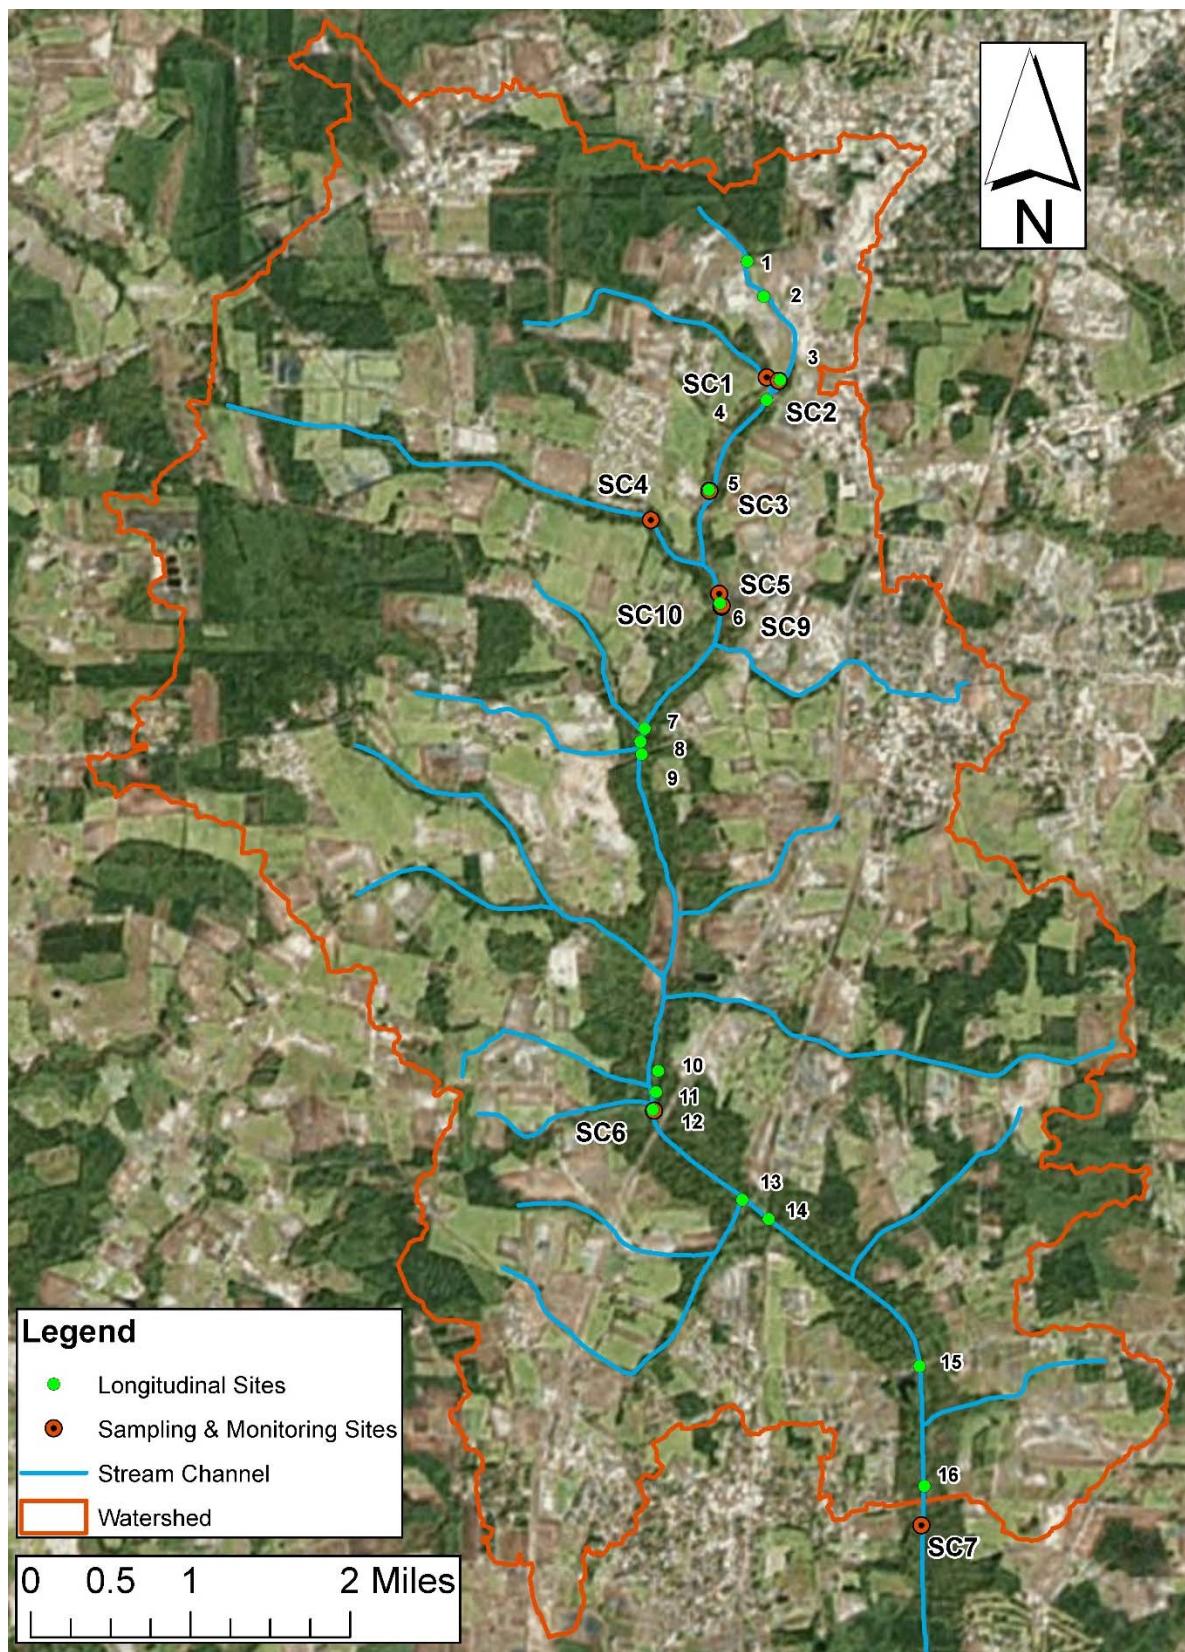

Figure 3. Swift Creek sampling and monitoring sites (SC 1-7, 9, 10; orange target symbols) and longitudinal sampling sites (1-16; green dots)

RESULTS AND DISCUSSION

Stream Flow

During the monitoring period (October 2014 - September 2015), baseflow was generally elevated during the late fall, winter, and early spring. During late spring, summer and early fall, baseflow was typically low (Figure 4). Data from the SC5 (Figure 4) is representative of discharge fluctuations at SC2 and SC6, included in Appendix A. Flow at SC6 was greater than at SC5 due to the larger watershed area, while flow at SC2 was less than at SC5 due to a smaller watershed area. Based on the discharge data, the October 2014 and February 2015 baseflow sampling events were during periods with greater baseflow and the April and August 2015 events were during periods of lower baseflow, presumably this could result in less dilution of non-point source contaminants on these dates.

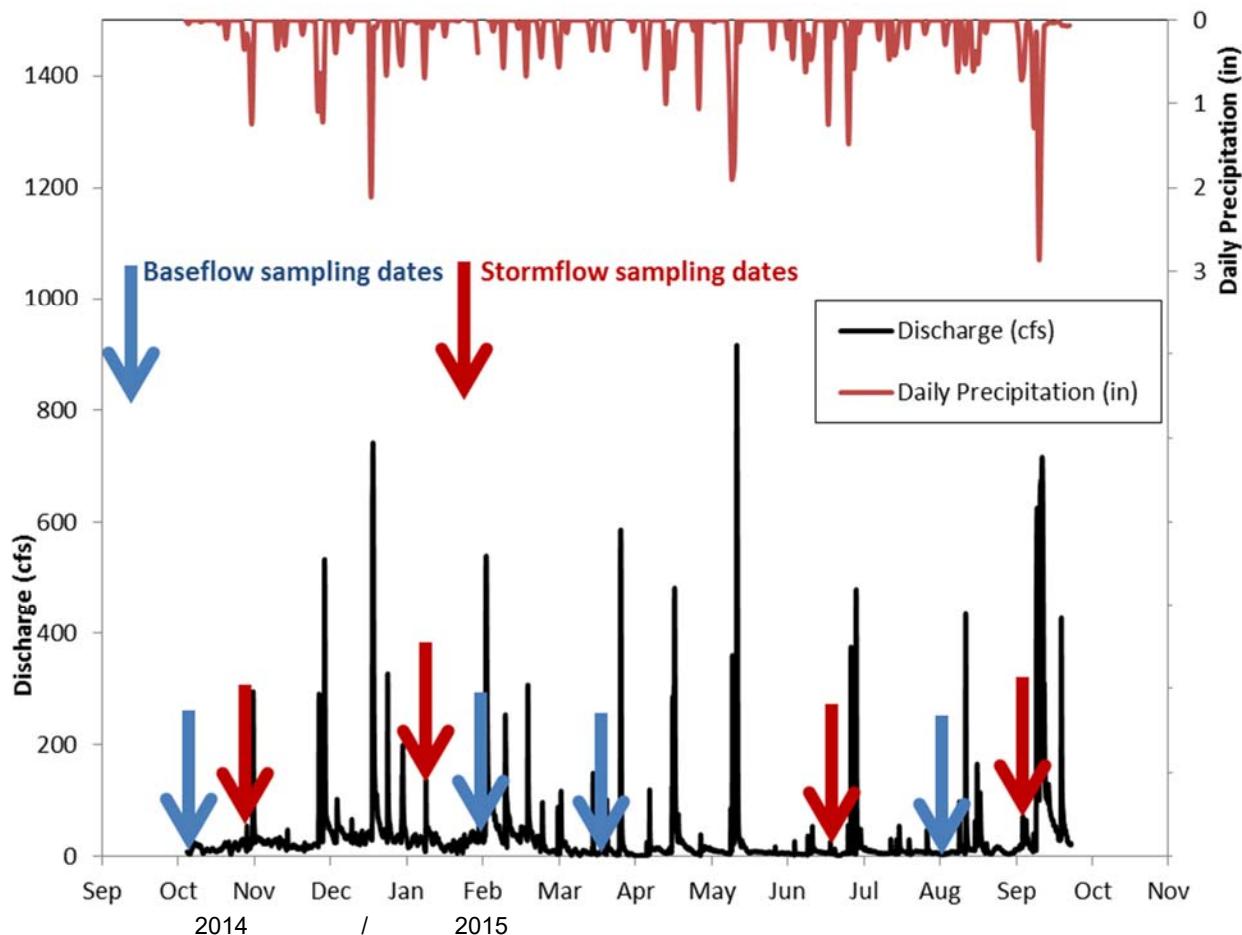

Figure 4. Swift Creek discharge data collected at station SC5 compared to precipitation inputs over the course of the study. Baseflow and storm flow monitoring dates are indicated by blue and red arrows, respectively.

Water Quality

Turbidity

Turbidity is an indicator of water clarity and serves as a metric for suspended sediment and colored dissolved organic matter. The NC standard for turbidity in surface waters is 50 NTU (instantaneous) or 25 NTU (10 day average). Turbidity measurements exceeded 50 NTU at five sites, SC 3-7 during one event (November 24). The turbidity measurements were between 25 and 50 NTU on five other storm flow and three baseflow sampling events. All longitudinal measurements were less than 20 NTU. In general, median turbidity values at each site increased during storm flows compared to baseflow (Figure 5). This is likely related to the increase in suspended sediments that commonly occurs during storm flow events. In addition, flushing of organic rich waters from riparian wetlands can also increase turbidity during storm events in coastal plain streams

Median storm flow turbidity at SC1 and SC2 were both 22 NTU. Runoff from active urban development in the headwaters upstream of SC 1 and SC 2 is likely mobilizing sediments into SC. Downstream, median storm flow turbidity increased from 13 NTU at SC3 to 24 NTU at SC 7. Agricultural runoff between SC 5 and SC 7 is likely the cause of increased turbidity at these downstream locations.

Baseflow turbidity measurements tended to decline downstream as shown by medians in Figure 5 and longitudinal survey measurements in Figure 6. . During the longitudinal surveys, there was a great deal of variability in baseflow turbidity measurements for the August sampling event (Figure 6), which may be related to increased algal growth during summer months at certain sites.

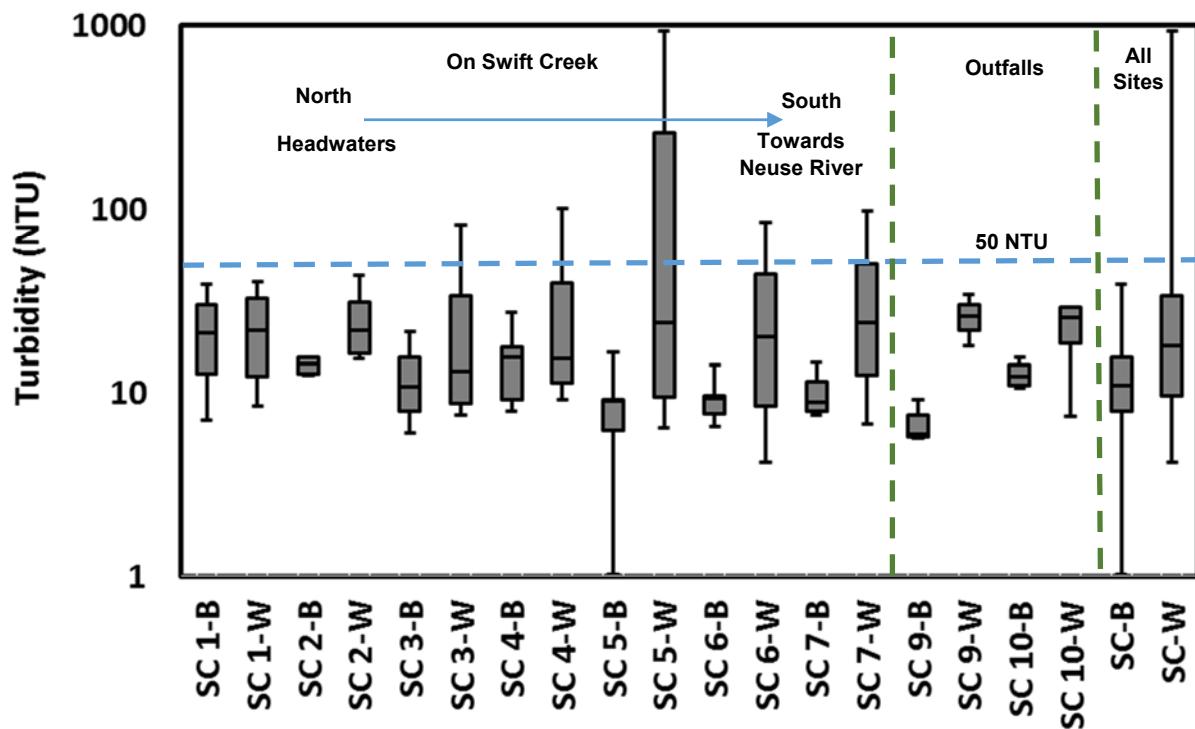

Figure 5. Box and whisker plots of turbidity measurements collected during baseflow (B) and storm or wet weather (W) flow conditions. Instantaneous turbidity limit of 50 NTU displayed for reference.

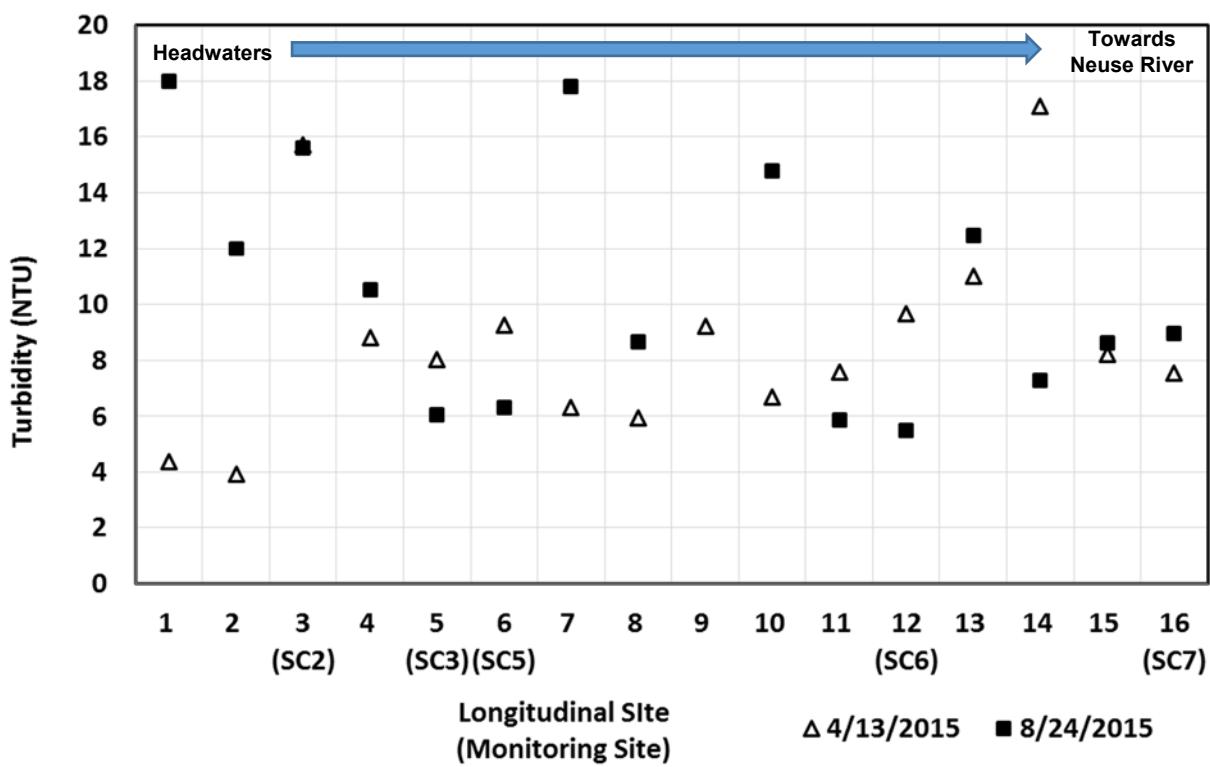

Figure 6. Swift Creek turbidity data collected during longitudinal surveys.

Total Suspended Solids

Storm flow TSS concentrations were generally higher than baseflow TSS values at each site, and storm flow medians were greater than corresponding base flow medians at each site (Figure 7). Although there is not a standard for most streams, NC has a TSS standard for high quality waters set at 20 mg/l. All but one baseflow sample had TSS concentrations less than this standard, while TSS concentrations during two storms exceeded 20 mg/l at nearly all in-stream sites, but only one site (SC2) exceeded 20 mg/l for the remaining two storms. The main pattern observed in TSS data was elevated TSS during storm events, with the greatest concentrations at SC5 and SC6, where TSS during storm events could be elevated to greater than 1000 mg/l (Figure 7). The two outfalls each exceeded 20 mg/l during three storms, while baseflow concentrations were typically lower.

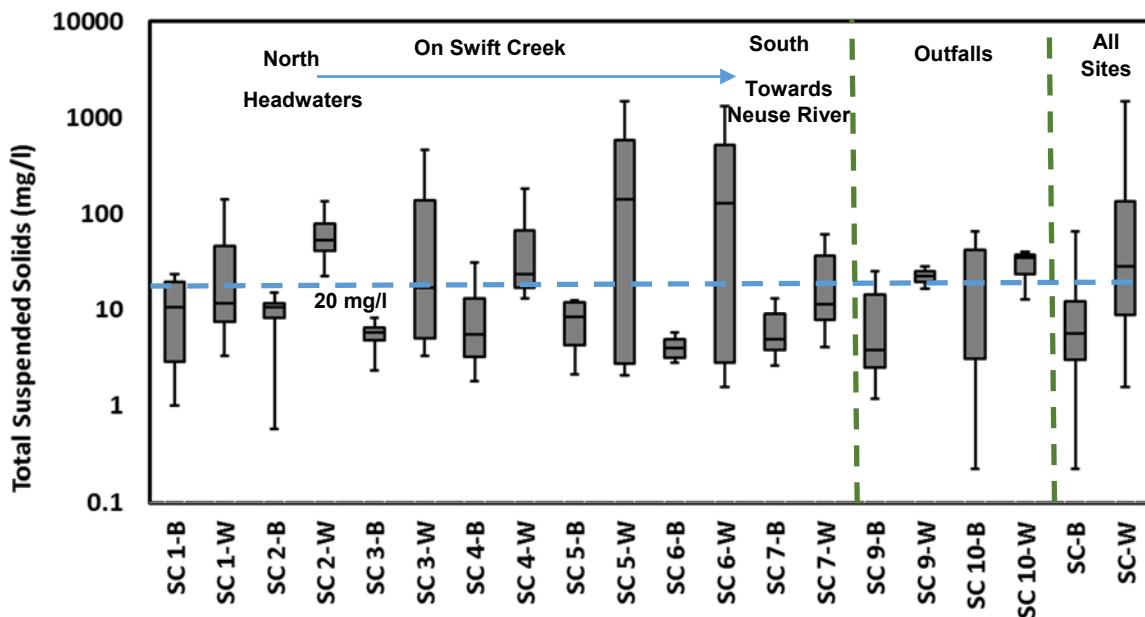

Figure 7. Swift Creek total suspended solids data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC 9 and SC10 are outfalls. The 20 mg/l for TSS in High Quality Waters is shown for reference.

Dissolved Organic Carbon

Dissolved Organic Carbon (DOC) does not have a water quality criteria. It is produced by the decomposition of organic substances, commonly in streams or wetlands.

Dissolved organic carbon (DOC) was relatively low in headwaters baseflow samples, and generally increased downstream, particularly between stations SC5 and SC7 (Figure 8). At most sites, there was an increase in DOC during storm events. This indicates a stormwater-related source which could include flushing of organics from wetlands and riparian areas, although leaking wastewater infrastructure may be a contributor as well.

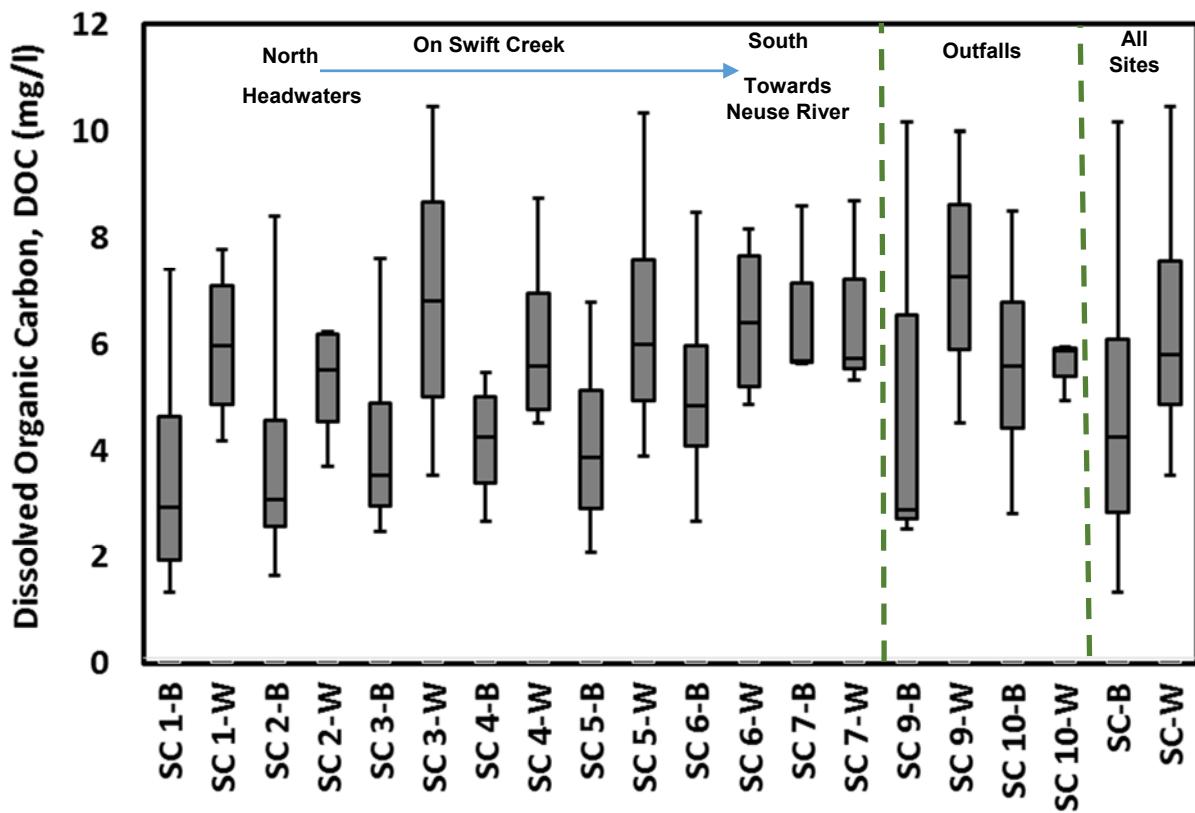

Figure 8. Swift Creek dissolved organic carbon concentration data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC 9 and 10 are outfalls.

Specific Conductivity

Specific conductivity provides an indication of the concentration of dissolved ions in the water. It can also be used to indicate significant changes in water chemistry such as from wastewater or road salts. Chloride (Cl) is a primary ion in common salts. Since fluctuations of Cl concentrations and SC measurements were nearly identical, Cl results are included in Appendix C.

Median base flow specific conductivity values were greater for base flow than storm flow for all sites. Conductivity logger plots for SC2, SC5, and SC6 (included in Appendix B) generally showed a similar pattern of a sharp spike in conductivity at the beginning of storm events, followed by a sharp decrease as storm events extended, and increasing towards an equilibrium value following events as the end of the storm hydrograph and interflow taper off.

Conductivity values were generally less than 0.10 mS/cm throughout the record, except during a period in late January and March at SC 6, following road salt applications in Pitt County due to ice and snow events. Base flow conductivities decreased noticeably from late winter into summer before rising in the fall. This was likely due to agricultural drainage inputs fluctuating with groundwater elevation changes. Agricultural drainage made up a greater proportion of baseflow during the winter and late fall than in the summer. During the winter months, increased drainage transports leached dissolved

ions from fields, whereas in a lower water table during the summer reduced drainage flows and transport of drainage.

In general, the stormwater outfalls had the most variable data. There was a subtle increase in median specific conductivity values when comparing the forested and urbanized headwater reach (SC1) vs the farthest downstream reach (SC7) during baseflow and storm flow conditions (Figure 9). During the longitudinal surveys (Figure 10), the comparison between the wetter and cooler April sampling data and the drier and warmer August sampling dates, suggests a slight difference in dilution occurs seasonally related to seasonal variations in groundwater recharge, most noticeable upstream of SC5.

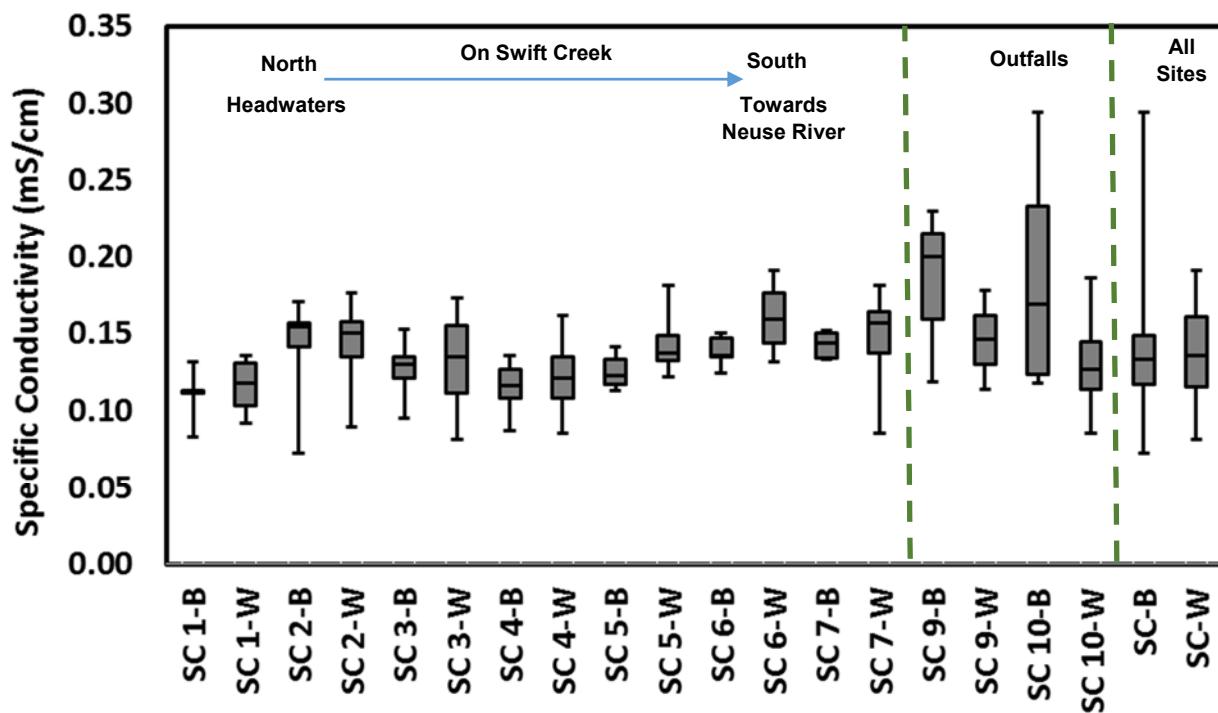

Figure 9. Swift Creek specific conductivity data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC 9 and 10 are outfalls.

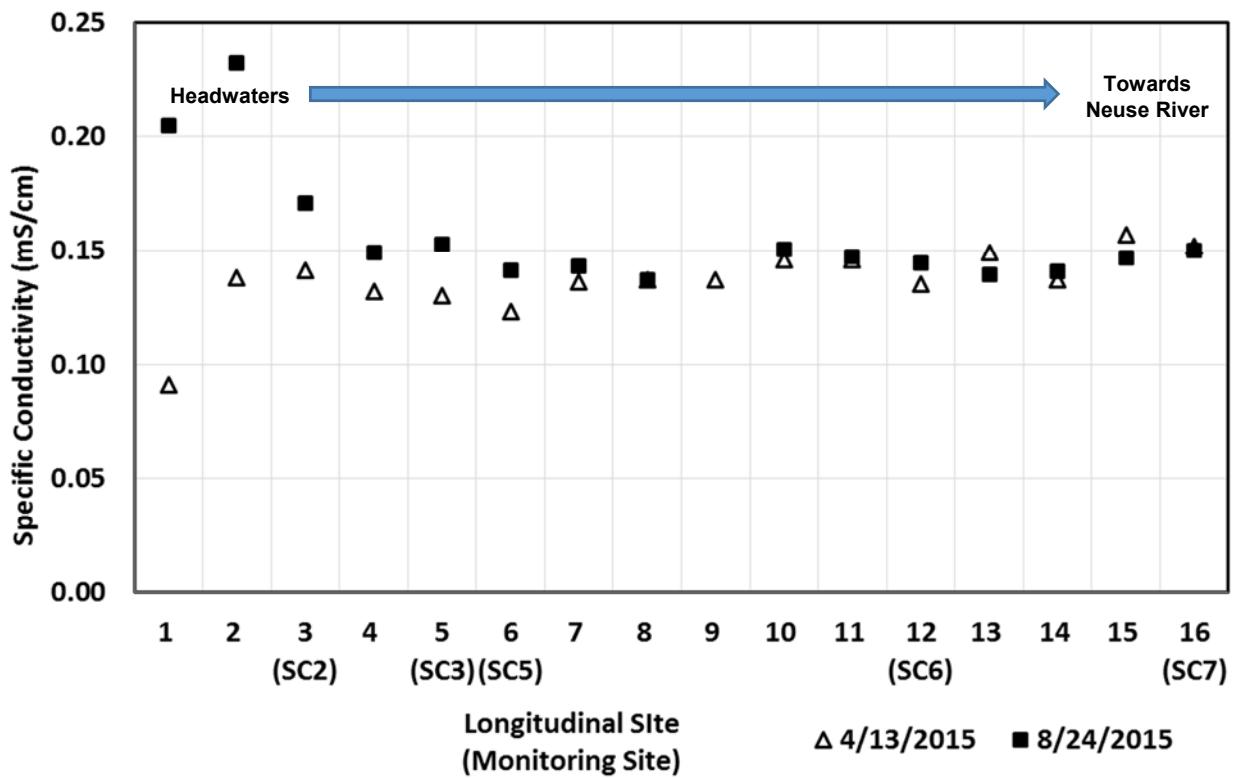

Figure 10. Swift Creek specific conductivity data collected during longitudinal surveys.

Total Dissolved Nitrogen

Nitrogen is an essential nutrient in the environment and can be transformed between different species through biological processes. Total Dissolved Nitrogen (TDN) includes Ammonium (NH_4), Nitrate and Nitrite (NO_{2+3}), and more complex dissolved forms of cumulatively referred to as Organic Nitrogen (ON). TDN concentrations for base flows and storm flows are summarized in Figure 11. Based on guidelines already developed in Florida, their criteria for TDN in streams ranges between 0.67-1.87 mg/l depending on the region. Median baseflow and storm flow concentrations exceeded 0.67 mg/l for all sites except SC 1 and SC 10 during baseflow, although only one sample exceeded 1.87 mg/l (Figure 11). Generally, ammonium concentrations were relatively low (<0.25 mg/l at all sites/dates; see Appendix C for data plots), while nitrate was the dominant form of inorganic nitrogen found in Swift Creek samples (typically >0.25 mg/l).

Median storm flow concentrations were typically greater than baseflow concentrations for all in-stream and outfall sampling sites (Figure 11). Storm flow and baseflow concentrations were less variable for instream samples from sites upstream of SC 6 and had similar baseflow and storm flow trends. Concentrations tended to increase from the headwater sites, SC 1 and SC 2, towards SC 3. Higher concentrations from a tributary, SC 4, corresponded with slightly higher concentrations at SC 5 than upstream at SC 3. Baseflow and storm flow concentrations were similarly variable at SC 6 for baseflow and storm flow, increasing slightly from SC 5. Baseflow concentrations at SC 7 were greater than SC 6, however, storm flow concentrations slightly lower than at SC 6. Baseflow

concentrations were greater for the February and April samplings than the August and October samples. This corresponded with changes in specific conductivity and corresponds with greater transport of TDN during periods with higher water tables and increased agricultural drainage.

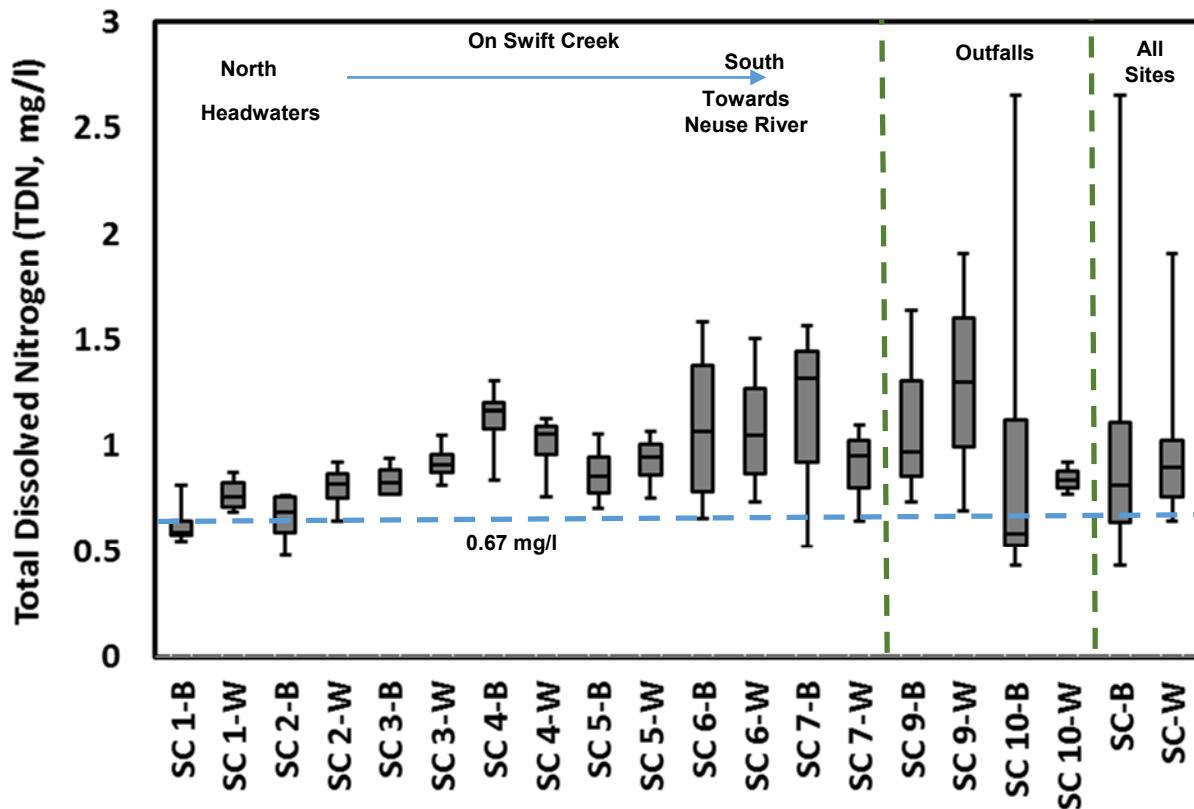

Figure 11. Swift Creek total nitrogen concentration data collected during baseflow (B) and storm flow or wet weather (W) conditions. SC9 and SC10 are stormwater outfalls. The guideline concentration of 0.67 mg/l of TDN for Florida is shown for reference.

Nitrate and Nitrite

Nitrate & nitrite (NO_{2+3}) concentrations for base flows and storm flows are summarized in Figure 12. Reference streams (undisturbed, forested watersheds) in the southeastern Coastal Plain generally have nitrate concentrations below 0.3 mg/l (EPA, 2000), in contrast SC sites typically had nitrate concentrations greater than 0.3 mg/l indicating anthropogenic nitrate inputs are affecting downstream waters. The nitrate concentrations during baseflow conditions generally increased with distance downstream from headwaters (Figure 12), and median storm flow concentrations were less than base flow concentrations. At the lower portions of the study watershed, median nitrate concentrations were > 1 mg/l (SC 6 & SC 7) with the highest median concentration of 1.90 mg/l at an outfall, SC 10. The greatest base flow concentrations at each in-stream site occurred in February. Elevated concentrations were likely due to increased agricultural drainage during a period when groundwater levels were likely highest of all base flow sampling dates. These data and the general decline in nitrate

concentration during storm flow events indicate that groundwater transport of nitrate to the channel results in increasing concentrations downstream.

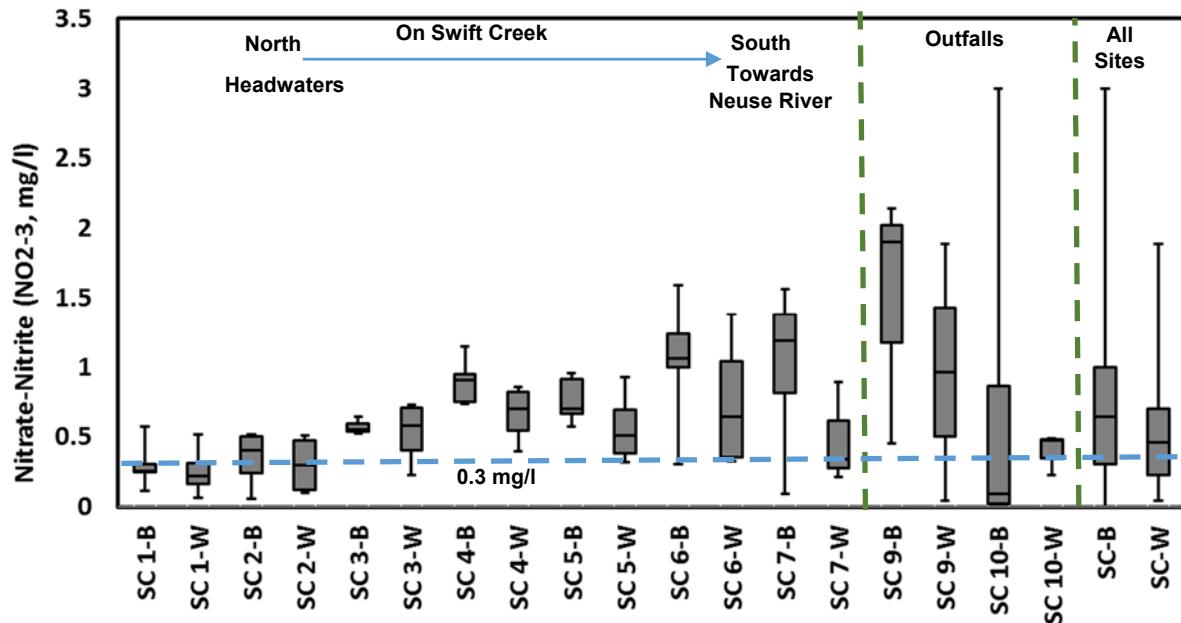

Figure 12. Swift Creek nitrate concentration data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC 9 and 10 are outfalls. The estimate of 0.3 mg/l for nitrate in undisturbed coastal plain forests is shown for reference.

¹⁵N and ¹⁸O Isotopes in NO₃

To help identify the source of NO₂₊₃ during storm flows, samples from each site were collected on August 24 (base flow) and September 25 (storm flow) at each site for analyses of ¹⁵N and ¹⁸O isotopes in NO₃. Since N in fertilizer is typically derived from atmospheric N, which is the reference standard used for $\delta^{15}\text{N}$, ¹⁵N in nitrate derived from fertilizer is typically found at low levels (depleted) and the $\delta^{15}\text{N}$ composition of fertilizer should be close to 0 (Kendall et al. 2007). Since denitrifying bacteria reduce and remove nitrate from surface waters, and the bacteria preferentially remove the lighter ¹⁴N, the remaining nitrate becomes enriched with ¹⁵N. Similarly ¹⁸O becomes enriched as denitrification occurs. Therefore, as waters with nitrate experience denitrification the ¹⁵N and ¹⁸O become enriched in the nitrate pool remaining in the water. This means that samples with ¹⁵N values that are enriched may also suggest a nitrate source that was initially less enriched, if denitrification occurred as the nitrate cycled through the watershed. This trend is shown indicated by the denitrification arrow in Figure 13.

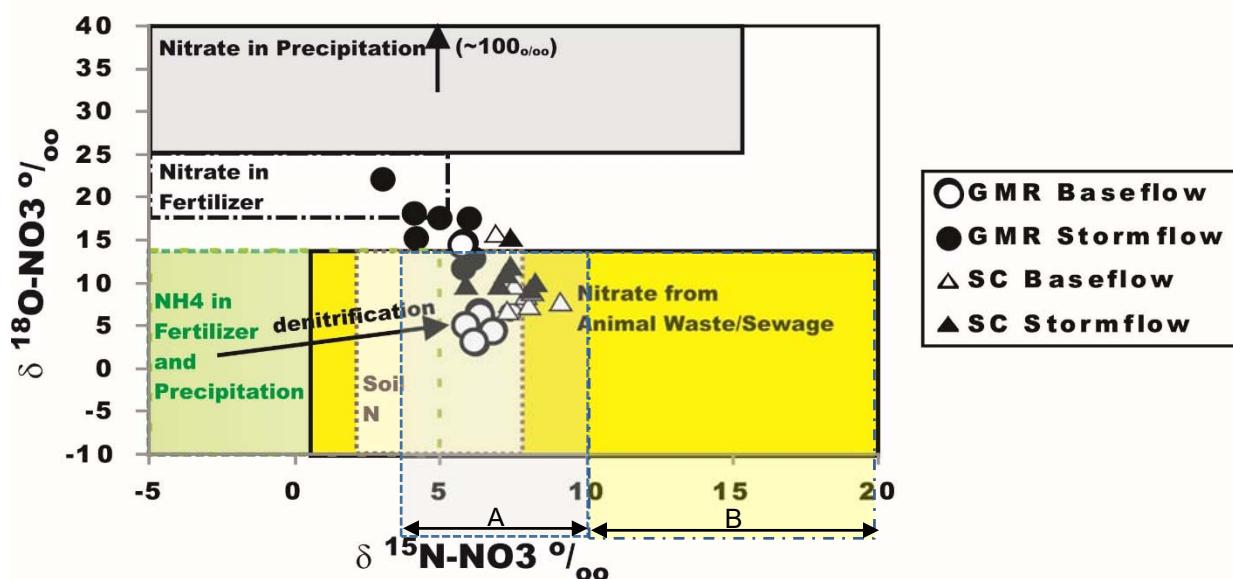

Figure 13. ^{15}N and ^{18}O isotopes in nitrate measured at sampling stations along Swift Creek (SC) and Greens Mill Run (GMR) overlain on the source ranges (shaded) presented by Kendall et al. (2007). Sample collection for isotopic analyses occurred on 8/24/2015 (baseflow) and 9/25/2015 (storm flow). A: Fertilizer ^{15}N 25-75th per centile range measured under crop fields and golf courses in eastern North Carolina (Spruill et al. 2002). B: Waste ^{15}N 25-75th percentile range measured under septic drainfields, poultry, and hog farms in eastern North Carolina (Spruill et al. 2002, Iverson et al. 2015).

In Figure 13, the majority of samples fall in the range corresponding to soil and waste sources provided by Kendall et al. (2007). The ranges for nitrate sources from Kendall et al. (2007) are based on a broad range of data sources. Although the general ranges presented by Kendall et al. (2007) may represent the initial fertilizer sources in eastern North Carolina, it appears that there may be an offset as the nitrate sourced from fertilizer migrates through the soils, to the groundwater, and ultimately to a stream or wetland. Local work by Spruill et al. (2002) provided a tighter range of ^{15}N values for groundwater underlying croplands and golf courses (most fertilizer sources had ^{15}N from 4-10 ‰) and underlying septic, poultry, and hog waste (most waste sources had ^{15}N from 10 to 22 ‰). Spruill et al. (2002) used a cutoff for ^{15}N of 10 ‰ to discriminate between fertilizer and waste sources. In addition, Iverson et al. (2015) measured septic drainfield ^{15}N in Pitt County and their median ^{15}N value for 8 measurements was approximately 18 ‰ for groundwater and 11 ‰ for streams adjacent to septic systems. Recent work in Beaufort County by O'Driscoll et al. (2014) traced a septic plume and found that wastewater-affected groundwater was indicated by ^{15}N compositions of approximately 10 ‰ or greater. Overall, these regional datasets suggest that wastewater in eastern NC tends to be on the enriched side of the range provided by Kendall et al. (2007), generally > 10 ‰ $^{15}\text{N-NO}_3$. The study by Spruill et al. (2002) measured ^{15}N in groundwater of the North Carolina Coastal Plain. Their data showed enriched fertilizer ^{15}N relative to the ranges provided by Kendall and others (2007). It is likely that the enrichment that occurs between fertilizer application and transport to the groundwater (presumably linked to denitrification or mixing with more enriched soil N or wastewater sources) can explain this offset. We included the Spruill

et al. (2002) data in Figure 13, as those may provide a tighter range for comparison with regional $\delta^{15}\text{N}$ data. Based on these data, the $\delta^{15}\text{N}$ range of our current study samples during late summer and early fall suggest fertilizer or soil N as the dominant source of nitrate in SC. However, wastewater influences could not be ruled out because when mixed with fertilizer or soil N sources, wastewater sources would tend to enrich samples and there were locations where enrichment was observed, particularly within Swift Creek.

To evaluate if mixing or denitrification is the mechanism for enrichment of $\delta^{15}\text{N}$, a plot of $\text{NO}_3\text{-N}$ vs $\delta^{15}\text{N-NO}_3$ can provide insights. If denitrification is the mechanism for $\delta^{15}\text{N}$ enrichment, then an inverse relationship is expected between $\text{NO}_3\text{-N}$ and $\delta^{15}\text{N}$, whereas if mixing with enriched sources of $\delta^{15}\text{N}$ is the mechanism then $\delta^{15}\text{N}$ would increase with increasing $\text{NO}_3\text{-N}$ concentrations. These plots are shown in Figure 14 and suggest that that enriched $\delta^{15}\text{N}$ compositions in surface water are more likely related to mixing with enriched sources rather than denitrification along the channel. The pattern of similar $\delta^{15}\text{N}$ across the SC watershed during baseflow conditions suggests a similar source of nitrates during baseflow (Figure 14).

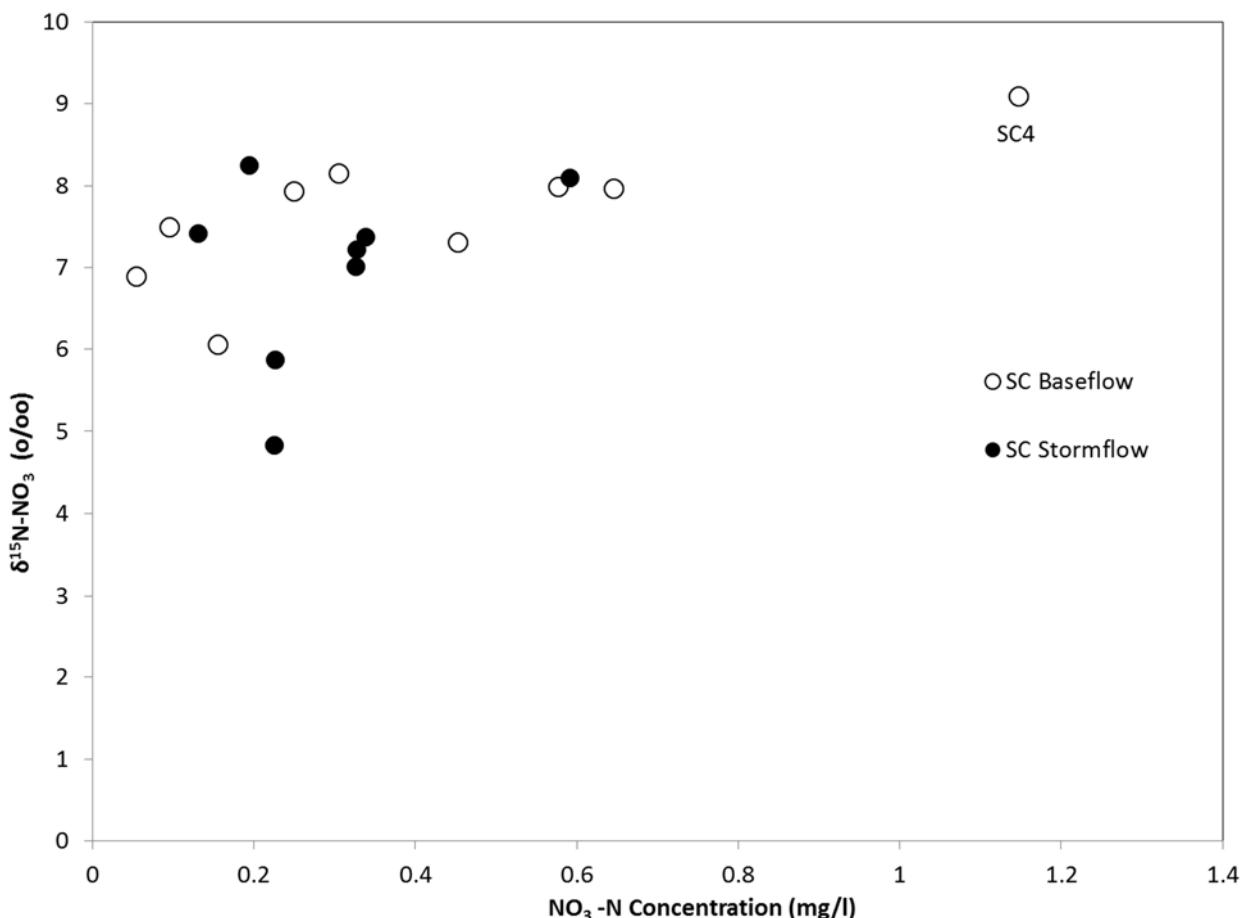

Figure 14. Nitrate ($\text{NO}_3\text{-N}$) vs $\delta^{15}\text{N}$ for SC for the baseflow (8/24/15) and storm (9/25/15) events.

For Swift Creek, some results are closer to the range of potential waste sources provided by Kendall et al. (2007). However, those samples do not fall in the regional range provided by Spruill et al. (2002). Most of Swift Creek watershed is served by septic systems. Therefore it is expected that wastewater nitrogen inputs to streams may occur in the Swift Creek watershed. Site SC4 in particular had nitrate with enriched $\delta^{15}\text{N}$, relative to the others. More monitoring and a comparison of septic vs. sewerered neighborhoods could help further determine the wastewater-related N-inputs. These and other data suggest that the Swift Creek tributary upstream of the SC4 monitoring point is causing increases in nitrogen along the main stem. Efforts to reduce contaminants along this tributary would likely improve water quality along the main stem.

Based on median values for baseflow ($7.94 \delta^{15}\text{N-NO}_3 \text{o/oo}$, $7.83 \delta^{18}\text{O-NO}_3 \text{o/oo}$), the $\delta^{15}\text{N}$ during baseflow along SC falls within the range of fertilizer (Spruill et al., 2002) or soil nitrogen (Kendall et al., 2007). From headwaters to the bottom of the watershed there was a subtle increase in $\delta^{15}\text{N}$ and $\delta^{18}\text{O}$ in nitrate during baseflow (Figure 15) and storm flow (Figure 16), suggesting some potential denitrification along the stream. The baseflow $\delta^{18}\text{O}$ in nitrate from SC2 was elevated (Figure 15), suggesting either lab error or a contrasting groundwater source from the other sites. However, since similar enrichment was observed during the storm event (Figure 16), it is unlikely that the enrichment was related to lab error.

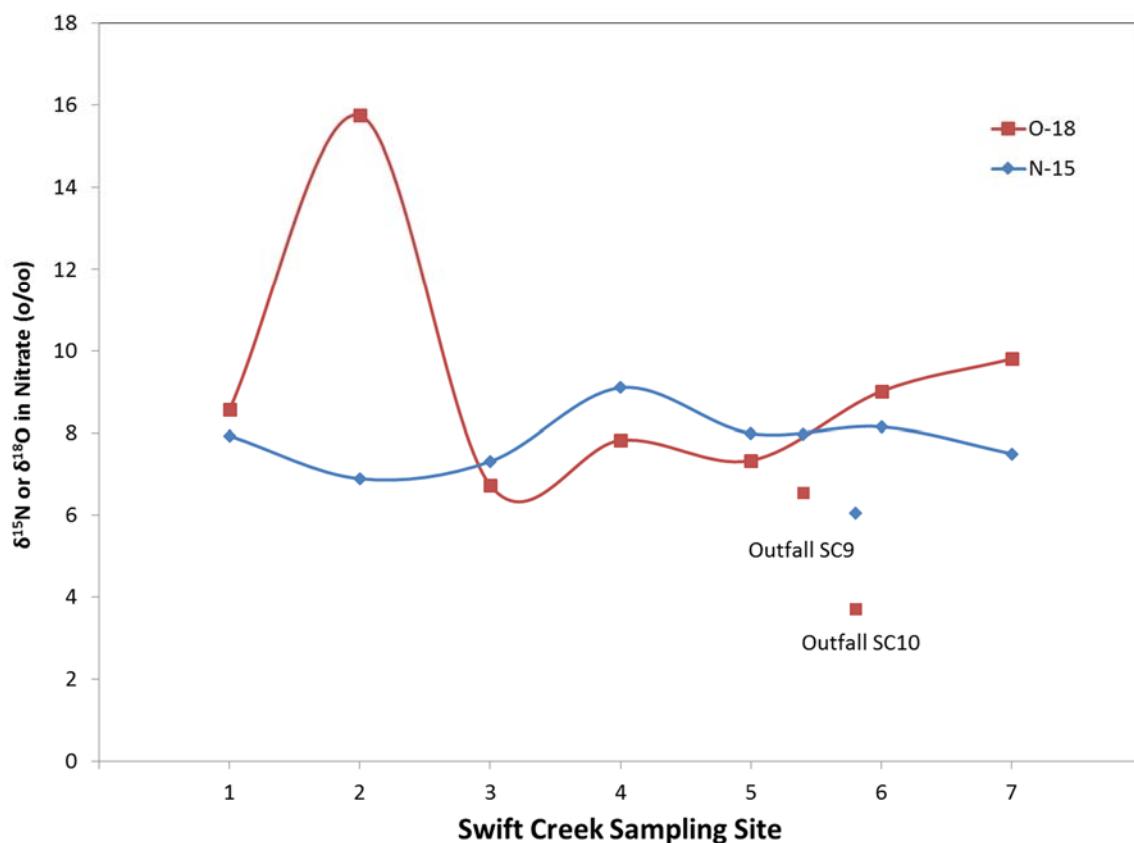

Figure 15. SC $\delta^{15}\text{N}$ and $\delta^{18}\text{O}$ in nitrate trends from headwaters to lowest monitoring point during baseflow.

During the storm event, there was a slight decline in $\delta^{15}\text{N}$ and enrichment in $\delta^{18}\text{O}$ from headwaters to SC3, suggesting stormwater inputs (Figure 16). The enrichment in $\delta^{15}\text{N}$ at SC4 suggests potentially enriched inputs, possibly wastewater (previously discussed). These data suggest mixing of multiple N sources during the storm event. The effects of stormwater inputs on Swift Creek are less pronounced relative to those observed on Greens Mill Run.

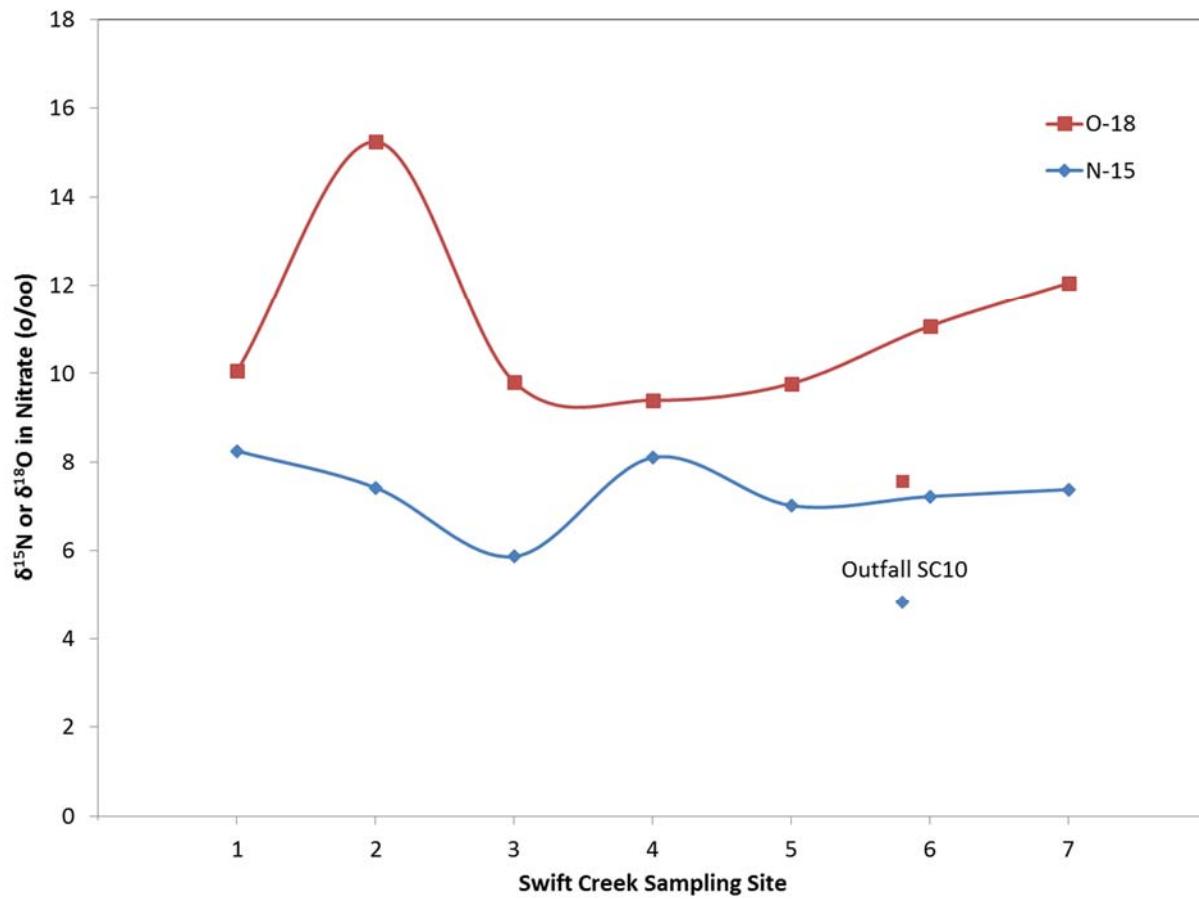

Figure 16. SC $\delta^{15}\text{N}$ and $\delta^{18}\text{O}$ in nitrate trends from headwaters to lowest monitoring point during storm flow.

Along Swift Creek, nitrate concentrations were most elevated at SC4, both during the baseflow event and the storm event. During baseflow conditions, chloride concentrations were similar at monitoring stations (Figure 17). During the storm event, differences in chloride concentration between the monitoring sites and outfall (10) became more pronounced, presumably due to dilution effects (Figure 18).

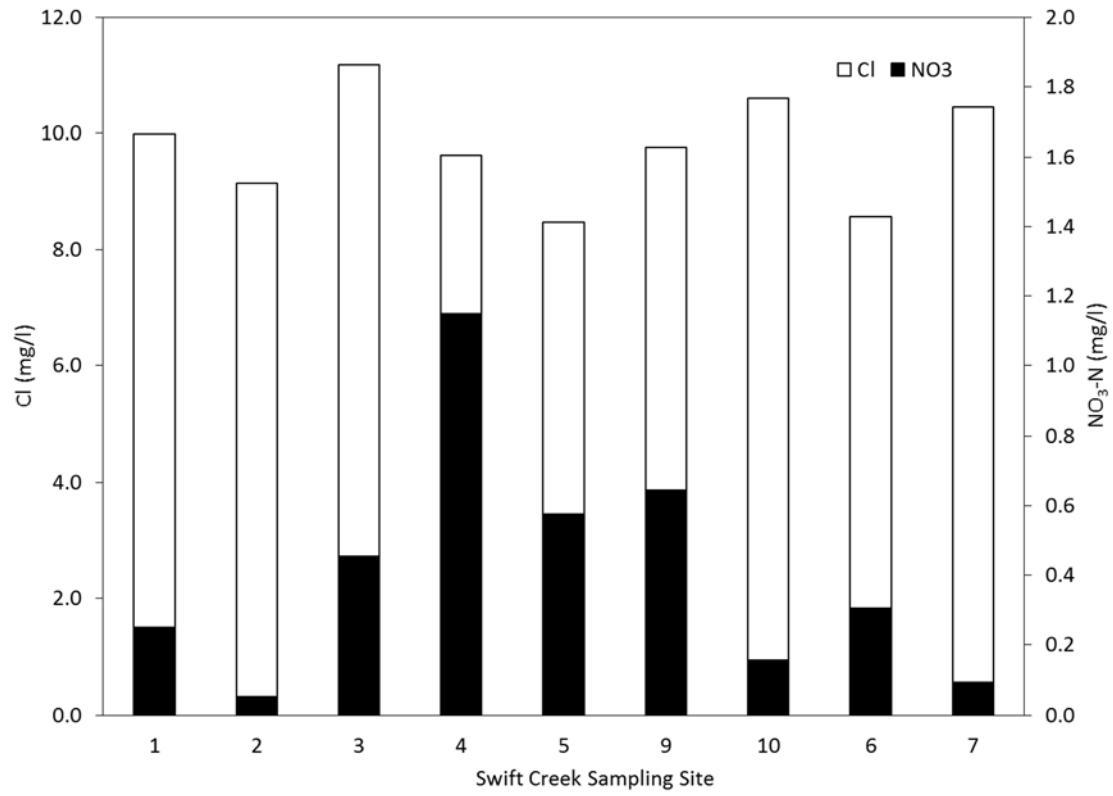

Figure 17. Nitrate and chloride concentrations along SC during baseflow event.

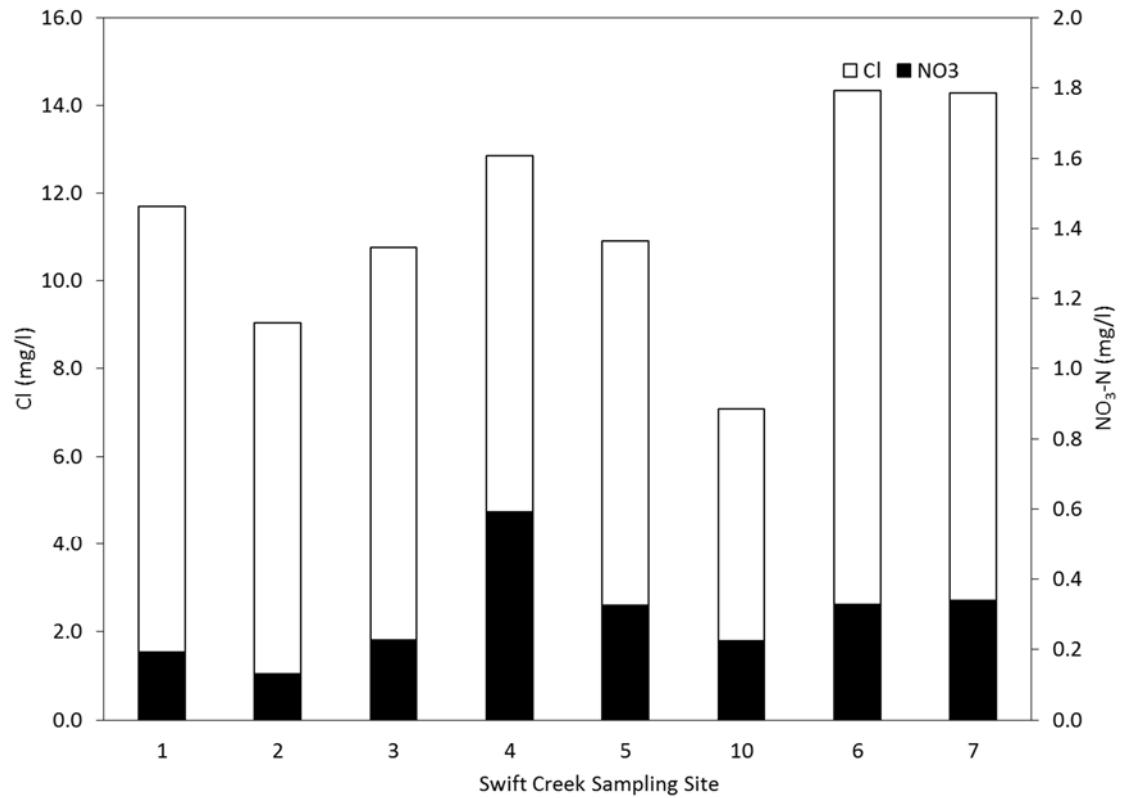

Figure 18. Nitrate and chloride concentrations along SC during storm event.

Overall, the data presented suggest that fertilizer and soil nitrogen inputs are likely the dominant nitrogen sources. However, more detailed year-round surface water and groundwater isotopic monitoring would be needed to better isolate the dominant sources with greater certainty. Since the isotopic sampling was only conducted for one baseflow and one storm event during the summer, it is likely that there is seasonal and intra-storm variability in isotopic composition, further isotopic sampling could help better elucidate the major sources of nitrate inputs to these streams.

Organic Nitrogen

Organic Nitrogen (ON) was relatively low in baseflow samples, but in contrast to nitrate it increased during runoff events (Figure 19). In some cases, during storm events ON was the dominant form of dissolved nitrogen in the stream. This indicates a stormwater-related source which could include flushing of organics from wetlands and riparian areas, and possibly leaking wastewater infrastructure. Although NC doesn't currently have a standard for nitrogen in streams, nitrogen criteria are being developed for the future.

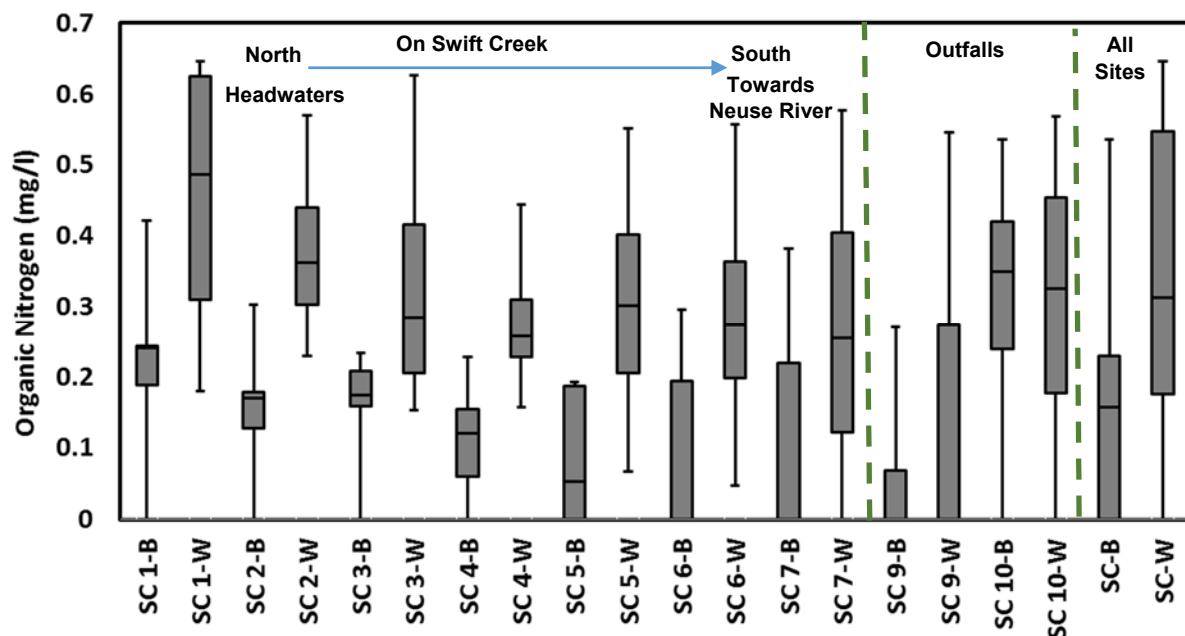

Figure 19. Swift Creek organic nitrogen concentration data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC9 and SC10 are outfalls.

Total Dissolved Phosphorus

Phosphorus is an essential nutrient in the environment as well and in excess can lead to algal blooms and eutrophication. Total Dissolved Phosphorus (TDP) includes phosphate (PO_4^{4-}) and other forms of soluble phosphorus. Based on guidelines already developed in Florida, criteria for TDP in streams range between 0.06 - 0.49 mg/l depending on the region. TDP along Swift Creek was generally lower during baseflow and typically increased during storm events. Based on guidelines already developed in Florida, criteria for TDP in streams ranges between 0.06-0.49 mg/l, depending on the region.

Along Swift Creek, during baseflow most sites had TDP concentrations that fell below or on the low end of this range, however as the watershed area increases downstream, most sites showed an increase in TDP concentrations, particularly during storm events. At all stream sites TDP was elevated above 0.06 mg/l during at least one storm event (Figure 20).

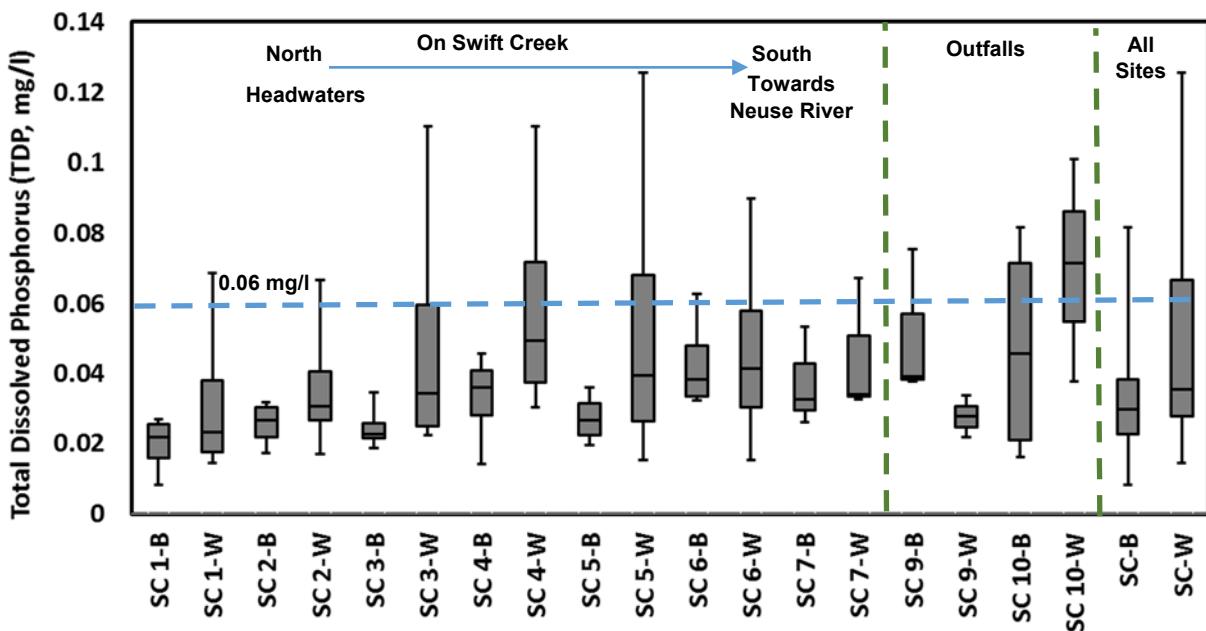

Figure 20. Swift Creek total dissolved phosphorus concentration data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC9 and 10 are outfalls. The guideline of 0.06 mg/l for TDP for Florida is shown for reference.

Dissolved Oxygen

North Carolina water quality standards (15A NCAC 2B) for dissolved oxygen for freshwater aquatic life is 5 mg/l (daily average), however there is no standard for streams classified as swamp waters. At SC 1, 2, 4, 6, and 7 dissolved oxygen was less than 5 mg/l on at least one date (Figure 21). The effects of low flows and warmer air temperatures on dissolved oxygen are evident in the longitudinal survey data (Figure 22). During the August longitudinal survey, most sites downstream of SC5 had dissolved oxygen concentrations below 5 mg/l. Low gradients, low streamflow, and warm temperatures can contribute to increased likelihood of low oxygen conditions in summer months. In addition, increased algal growth and decomposition can lead to dissolved oxygen declines.

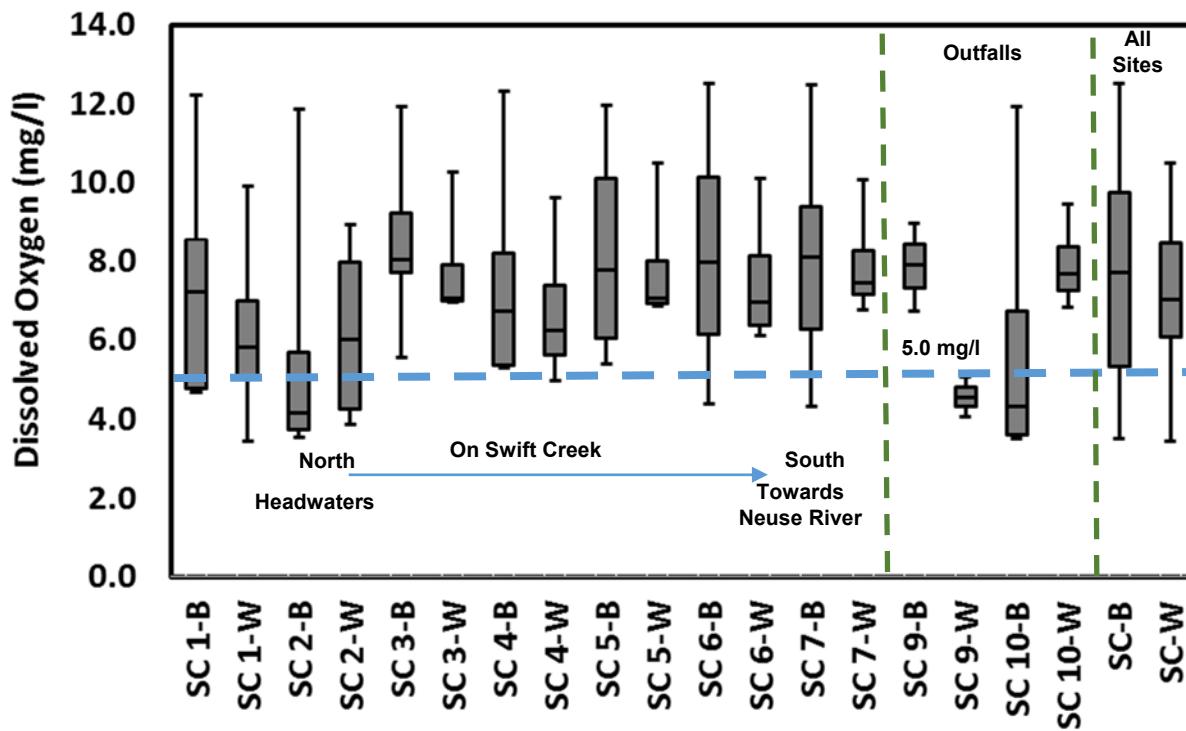

Figure 21. Swift Creek dissolved oxygen data collected during baseflow (B) and storm or wet weather (W) flow conditions. SC9 and 10 are outfalls. The NC standard daily average DO concentration of 5 mg/l is shown for reference.

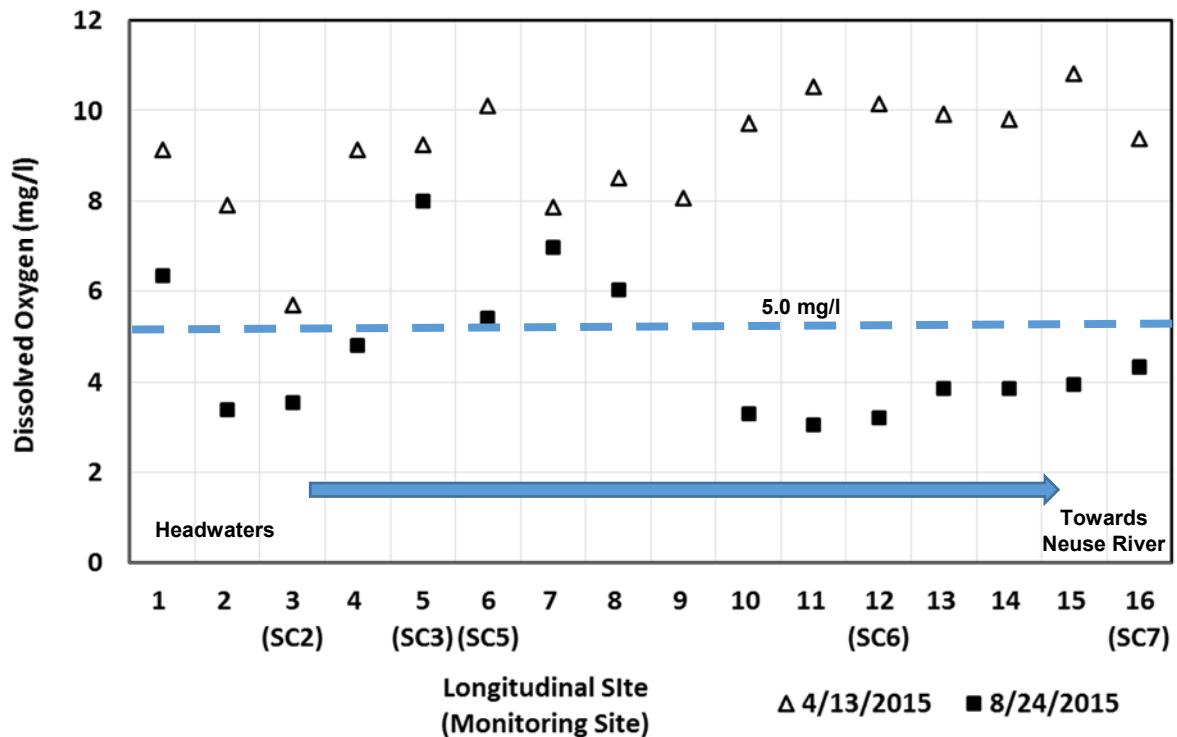

Figure 22. Swift Creek dissolved oxygen data collected during longitudinal surveys. The NC standard daily average DO concentration of 5 mg/l is shown for reference.

E. Coli & Total Coliform

E. coli is a species of fecal coliform bacteria used to indicate the presence of waste. The NC standard for *E. coli* in Class C waters is 576/100 ml or $10^{2.8}$. Analysis was mostly focused on *E. coli*, as that is the US EPA (1986) recommended indicator bacteria for fresh waters. As expected, total coliform concentrations were elevated relative to *E. coli* concentrations for each sampling location during baseflow and storm flow conditions. Total coliform concentrations were significantly higher ($p = 0.0003$) during baseflow and storm flow ($p = 0.0000$) than *E. coli* concentrations.

Storm flow *E. coli* concentrations were elevated relative to baseflow *E. coli* concentrations for 6 of the 7 sampling locations along SC (Figure 23). Statistically significant differences ($p = 0.0026$) were observed when comparing *E. coli* concentrations for all baseflow samples (geometric mean = 151 MPN/100 mL or $\log_{10} = 2.178$) to all storm flow samples (geometric mean = 487 MPN/100 mL or $\log_{10} = 2.687$). Similar trends were found regarding total coliform concentrations (Figure 24). More specifically, the total coliform concentrations were elevated during storm flow conditions (geometric mean = 2,756 MPN/100 mL or $\log_{10} = 3.440$) relative to baseflow conditions (geometric mean = 2,488 MPN/100 mL or $\log_{10} = 3.396$) for all sampling locations, and the differences between the baseflow and storm flow samples were statistically significant ($p = 0.0102$).

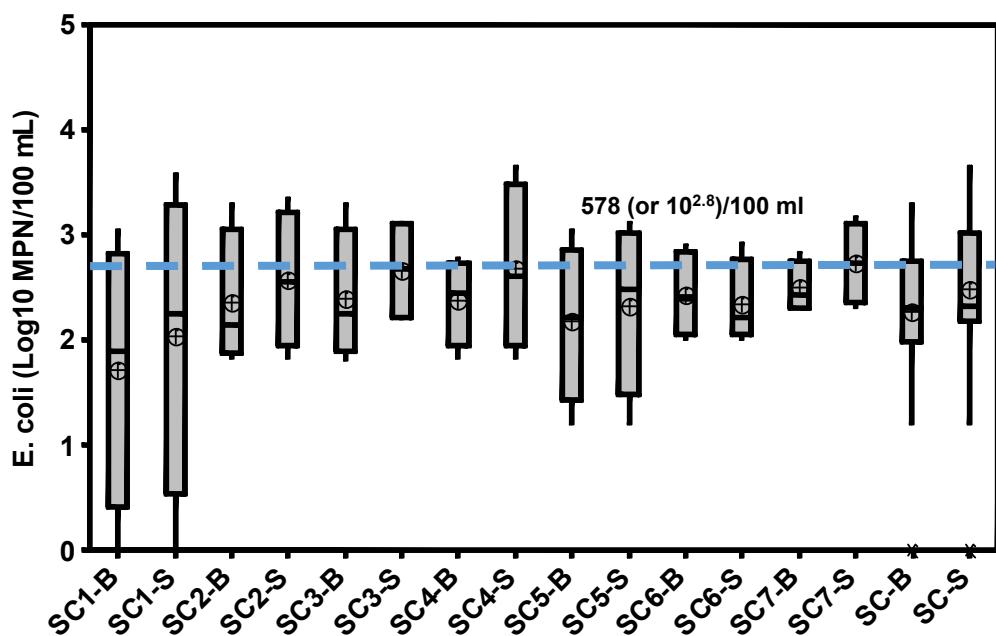

Figure 23. Baseflow (B) and storm (S) or wet weather flow *E. coli* concentrations for Swift Creek along 7 sampling locations (1-7), and the pooled data (SC-B, SC-S). The NC standard for *E. coli* of 578/100 ml ($10^{2.8}/100$ ml) is shown for reference.

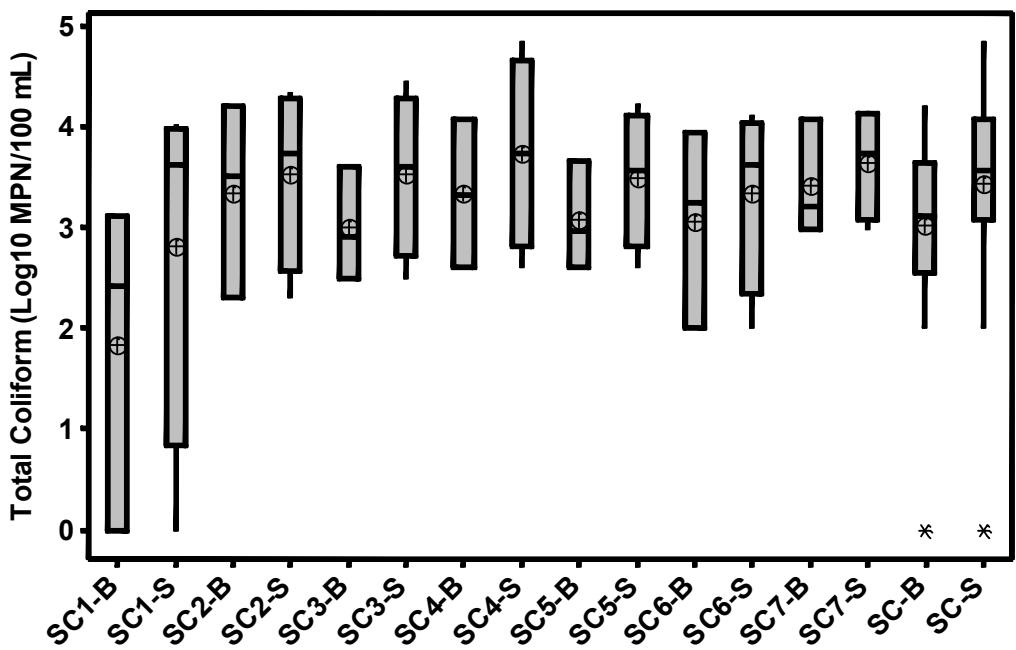

Figure 24. Swift Creek baseflow (B) and storm (S) or wet weather flow total coliform concentrations along 7 sampling locations (1-7), and the pooled data (SC-B, SC-S).

There is subtle evidence in the increasing *E. coli* with chloride and nitrate along Swift Creek during the storm event (Figure 25). These together may indicate wastewater as a source. In addition, the *E. coli* concentrations in Swift Creek during baseflow conditions typically increased along the main stem of the creek from SC 1 to SC 7. Notably, concentrations on two tributaries, SC2 and SC4, were higher than concentrations at monitoring sites on the main stem but upstream of the confluences, SC1 and SC5, respectively. The drainage areas upstream of SC2 and SC4 have substantial residential development, generally more than other areas within the watershed. Pet waste or poorly functioning septic systems could be contributing to elevated *E. coli* in these areas.

When temperatures are warmer, bacteria grow more quickly, and animals are more active and may contribute more waste to streams. Baseflow *E. coli* concentrations were lowest during the February sampling event (geometric mean = 35 MPN/100 mL or $\log_{10} = 1.542$), and highest during the October event (geometric mean = 1,079 MPN/100 mL or $\log_{10} = 3.033$). The August and April sampling events yielded intermediate *E. coli* concentrations with 97 MPN/100 mL ($\log_{10} = 1.985$) and 142 MPN/100 mL ($\log_{10} = 2.151$), respectively. *E. coli* concentrations were significantly higher in October relative to February ($p = 0.0020$), April ($p = 0.0021$), and August ($p = 0.0021$). The geometric mean *E. coli* concentrations during storm flow were lowest in February (85 MPN/100 mL or $\log_{10} = 1.929$), followed by July (612 MPN/100 mL or $\log_{10} = 2.786$), September (678 MPN/100 mL or $\log_{10} = 2.831$) and November (1,591 MPN/100 mL or $\log_{10} = 3.202$). Storm flow *E. coli* concentrations in February were significantly lower than in November ($p = 0.0017$), July ($p = 0.0130$) and September ($p = 0.0017$).

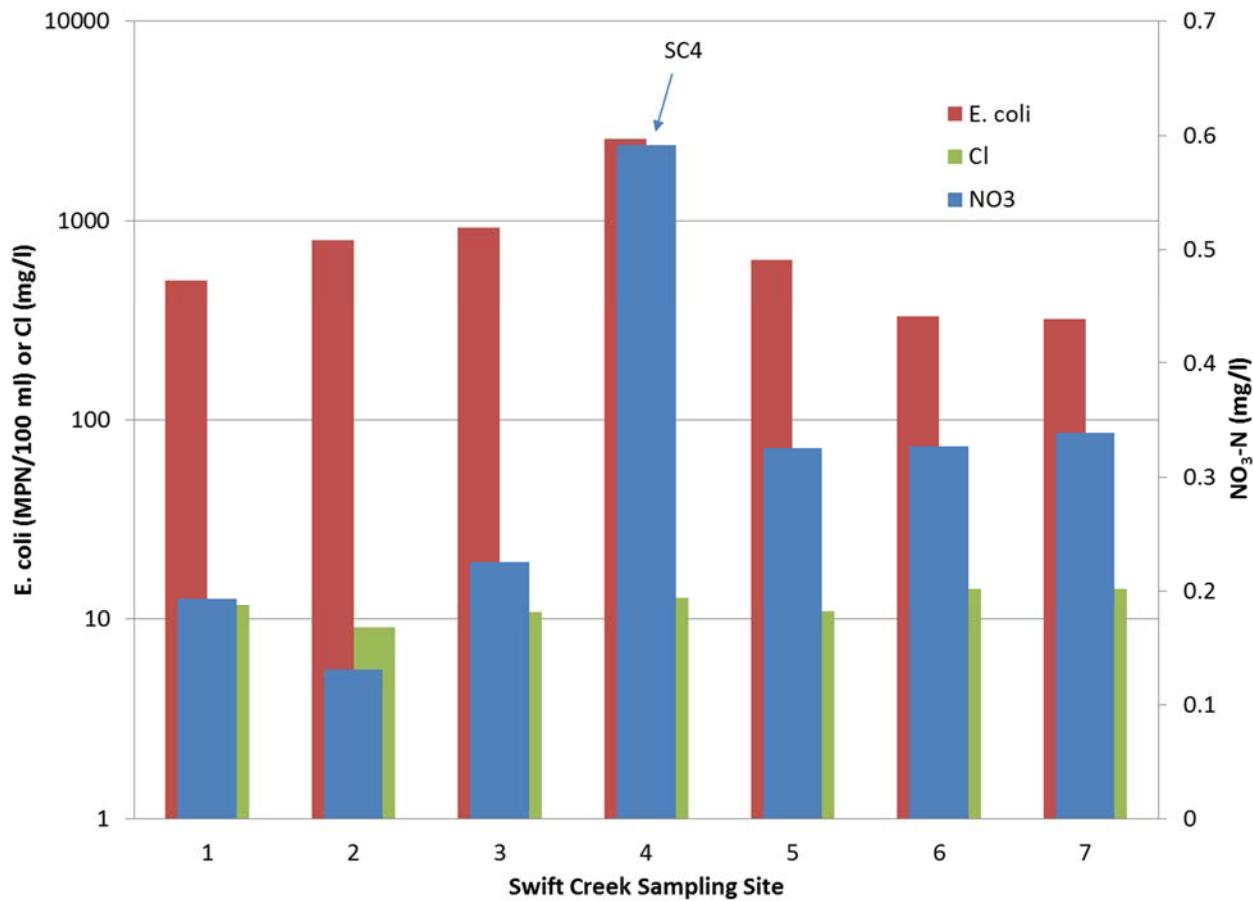

Figure 25. E.Coli, Cl, and NO₃ during the storm flow event sampled on 9/25/2015. From Swift Creek headwaters (1) to lowest monitoring station downstream (7).

Metals

All results of metals analyses (Table 3) were below detection for Copper and Lead, with Zinc concentrations only above detection at SC1 (both samples) and SC3 (storm flow). The NC water quality standard for Zn in freshwaters is 50 µg/l (ppb).

Table 3. Analytical results of metals analyses on baseflow and storm or wet weather flow samples.

| Monitoring Site | Baseflow | | | Storm (Wet Weather) Flow | | |
|-----------------|---------------|-------------|-------------|--------------------------|-------------|-------------|
| | 8/24/2015 | | | 9/25/2015 | | |
| | Copper (µg/l) | Lead (µg/l) | Zinc (µg/l) | Copper (µg/l) | Lead (µg/l) | Zinc (µg/l) |
| SC 1 | <10 | <5.0 | 13 | <10 | <5.0 | 11 |
| SC 3 | <10 | <5.0 | <10 | <10 | <5.0 | 11 |
| SC 5 | <10 | <5.0 | <10 | <10 | <5.0 | <10 |

*Analytical method for analysis of Copper and Zinc: EPA 200.7; Analytical method for analysis of Lead: Standard Method 3113B-04.

CONCLUSIONS AND RECOMMENDATIONS

Several indicators suggested that pollutant and sediment inputs increased downstream. In general most water quality parameters increased as the watershed area expanded (Table 4). However, during summer dissolved oxygen decreased in the lower portions of the watershed. Overall, the water quality data suggested that urban and agricultural land-uses in the watershed have contributed non-point source pollution resulting in increases in nutrient, sediment, and bacteria inputs to Swift Creek. Most water quality parameters, with the exception of nitrate and dissolved oxygen, increased with storm flow; suggesting that improved stormwater management could help reduce water quality impairment. The nitrate decline during storm events suggests a groundwater source of nitrate. Presumably this is related to agricultural fertilizer inputs as the increases correspond to the lower portions of the watershed that contain extensive agricultural drainage which are most evident during winter when agricultural drainage increases due to the shallower water table.

Table 4. General water quality trends associated with stormwater inputs and distance downstream. NC water quality standards are indicated with an asterisk.

| Runoff Events | Downstream | Standard* or Guideline Level | Standards or Guidelines Exceeded |
|----------------------------|--------------|------------------------------|----------------------------------|
| Specific Conductivity | ↑ ↑ | n/a | n/a |
| Dissolved Oxygen | ↓ ↑ ↓ summer | 5 mg/l* | Yes |
| Turbidity | ↑ ↔ ↑ storm | 50NTU* | Yes |
| Total Suspended Sediment | ↑ ↔ ↑ storm | 20 mg/l | Yes |
| Nitrate | ↓ ↑ | 0.3 mg/l | Yes |
| Dissolved Organic Nitrogen | ↑ ↔ | n/a | n/a |
| Total Dissolved Nitrogen | ↔ ↑ | 0.67 mg/l | Yes |
| Total Dissolved Phosphorus | ↑ ↑ | 0.06 mg/l | Yes |
| Dissolved Organic Carbon | ↑ ↑ baseflow | n/a | n/a |
| E. Coli | ↑ ↑ | 576/100ml* | Yes |
| Total Coliform | ↑ ↑ | n/a | n/a |

APPENDICES

APPENDIX A: Rating Curves and Discharge Records

Rating Curves

Rating curve equations for SC 2, SC 5, and SC 6 are listed below.

Table A1. Rating curve coefficients ($Q = C \cdot h^n$) for the three stage monitoring sites.

| Station | Rating Curve Coefficients | |
|---------|---------------------------|------|
| | C | n |
| SC 2 | 2.84 | 1.84 |
| SC 5 | 14.99 | 1.93 |
| SC 6 | 5.53 | 2.96 |

Discharge Records

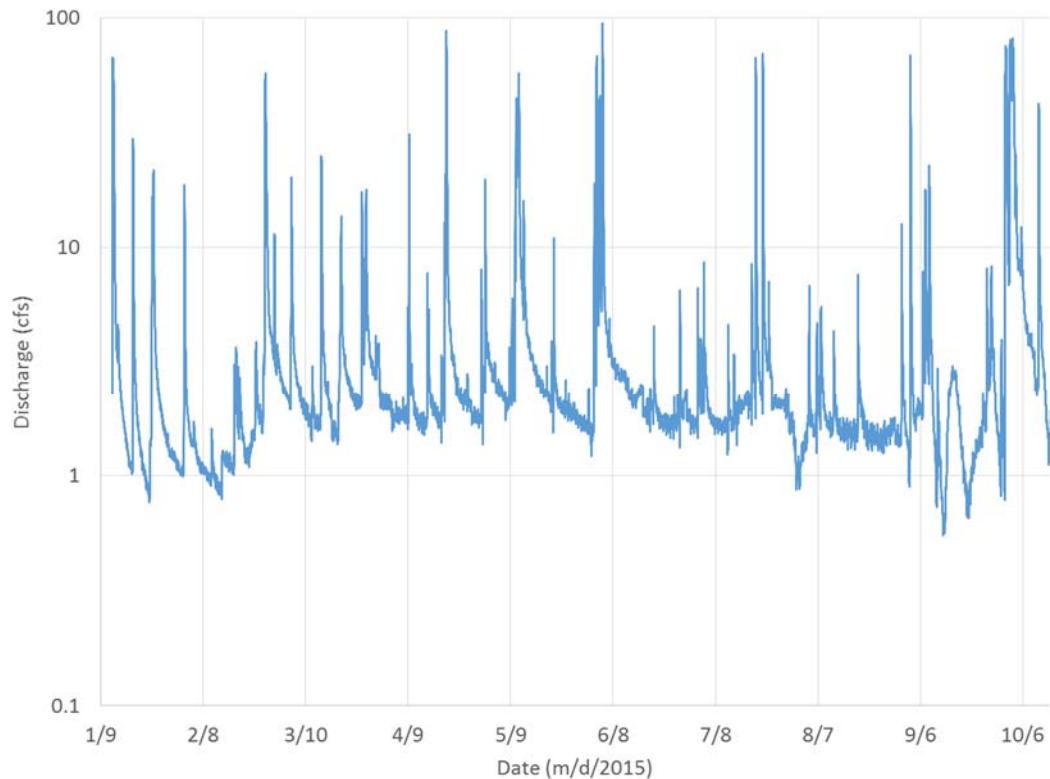

Figure A1. Discharge record for SC 2 monitoring site (January 9 - October 14, 2015).

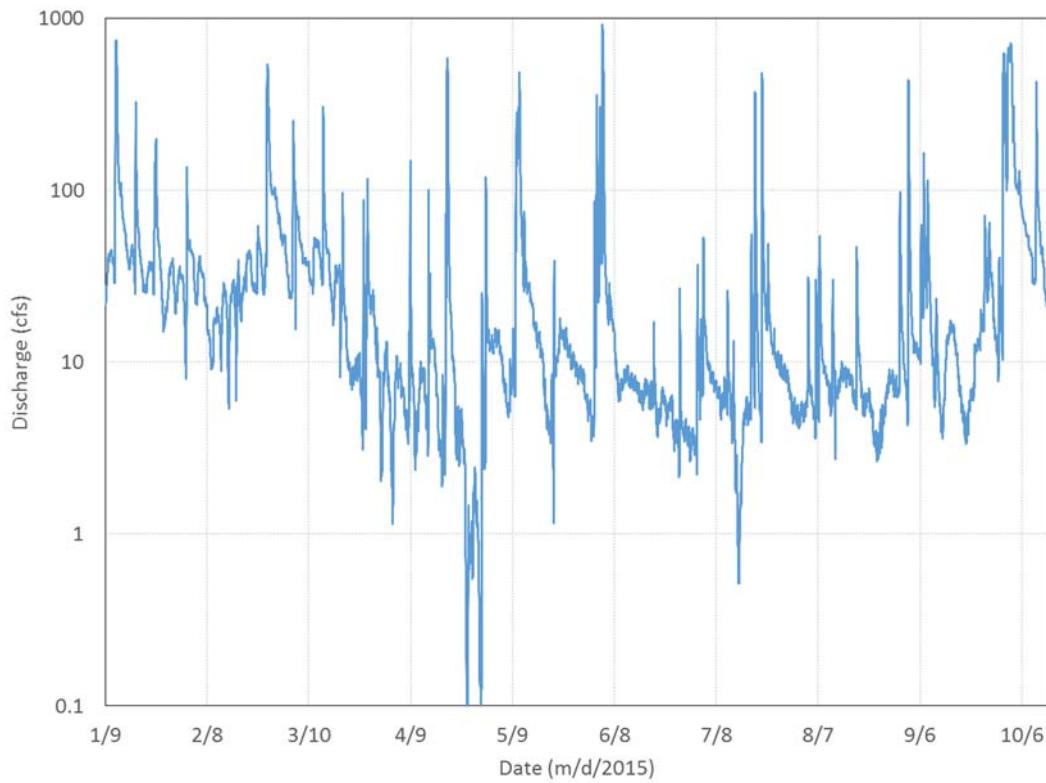

Figure A2. Discharge record for SC5 monitoring site (January 9 - October 14, 2015).

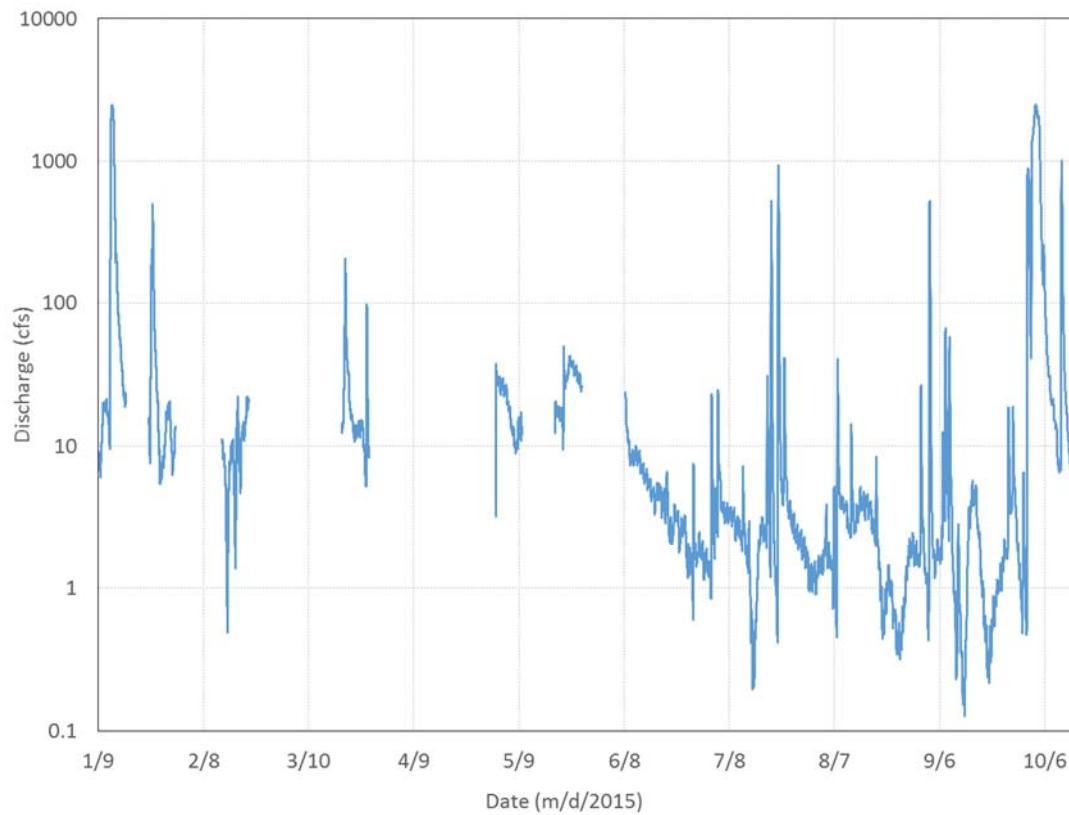

Figure A3. Discharge data for SC6 monitoring site (January 9 - October 14, 2015). Gaps in data resulted from improper configuration of logger.

APPENDIX B: Conductivity Records

A conductivity logger was initially installed at SC2. However, the logger was initially configured to log conductivity every 30 seconds, rather than every 30 minutes. In May, the logger was no longer recoverable from the stilling well at the monitoring station and was not replaced.

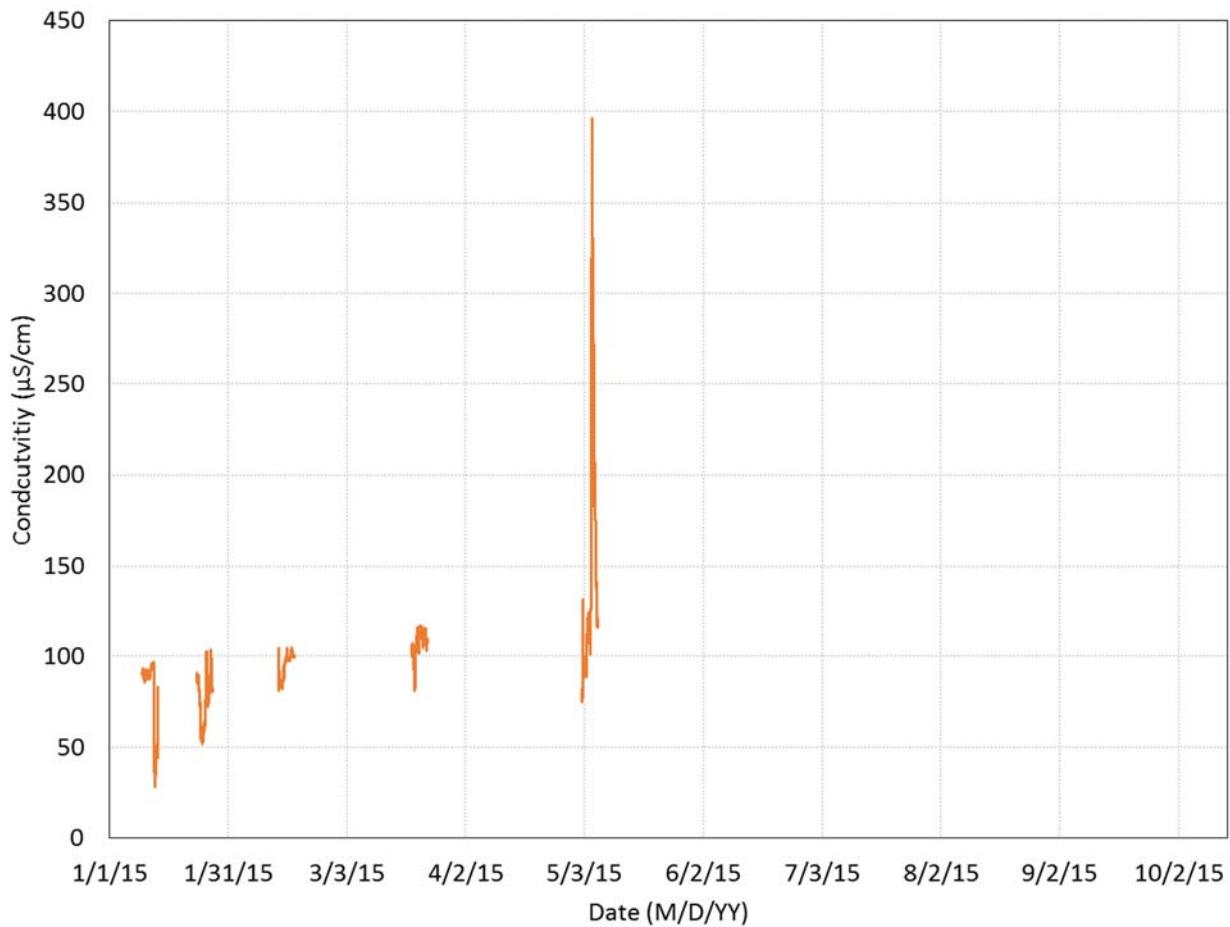

Figure B1. Conductivity Record for SC2 (January 9 - May 6, 2015).
